# Forward Induction in a Backward Inductive Manner* 

Martin Meier ${ }^{\dagger}$ and Andrés Perea ${ }^{\ddagger}$<br>EPICENTER Working Paper No. 27 (2023)<br><br>Research Center for<br>Epistemic Game Theory

#### Abstract

We propose a new rationalizability concept for dynamic games with imperfect information, forward and backward rationalizability, that combines elements from forward and backward induction reasoning. It proceeds by applying the forward induction concept of extensive-form rationalizability in a backward inductive fashion: It first applies extensive-form rationalizability from the last period onwards, subsequently from the penultimate period onwards, keeping the restrictions from the last period, and so on, until we reach the beginning of the game. We show that it is characterized epistemically by (a) first imposing common strong belief in rationality from the last period onwards, then (b) imposing common strong belief in rationality from the penultimate period onwards, keeping the restrictions imposed by (a), and so on. It turns out that in terms of outcomes, the concept is equivalent to the pure forward induction concept of extensive-form rationalizability, but both concepts may differ in terms of strategies. We argue that the new concept provides a more compelling theory for how players react to surprises. In terms of strategies, the new concept provides a refinement of the pure backward induction reasoning as embodied by backward dominance and backwards rationalizability. In fact, the new concept can be viewed as a backward looking strengthening of the forward looking concept of backwards rationalizability. Combining our results yields that every extensive-form rationalizable outcome is also backwards rationalizable. Finally, it is shown that the concept of forward and backward rationalizability satisfies the principle of supergame monotonicity: If a player learns that the game was actually preceded by some moves he was initially unaware of, then this new information will only refine, but never completely overthrow, his reasoning. Extensive-form rationalizability violates this principle.

## JEL Classification: C72

Keywords: Forward induction, backward induction, extensive-form rationalizability, backwards rationalizability, backward dominance, supergame monotonicity, dynamic games

Figure 1: Extensive-form rationalizability may lead to counterintuitive behavior

## 1 Introduction

The main feature that distinguishes dynamic games from static games is the issue of belief revision. That is, how does a player revise his belief upon observing a surprising move by an opponent? Backward induction and forward induction reasoning provide two different answers to this question.

The older idea is backward induction, which dates at least back to von Neumann and Morgenstern $(1953)^{1}$, and has also been incorporated in concepts like backwards rationalizability (Penta (2015), Perea (2014)), backward dominance (Perea (2014)), subgame perfect equilibrium (Selten (1965)), extensive-form perfect equilibrium (Selten (1975)), sequential equilibrium (Kreps and Wilson (1982)) and quasi-perfect equilibrium (van Damme (1984)). According to these concepts, upon reaching an unexpected information set a player is free to believe that this is due to mistakes by his opponents in executing their planned strategies. Hence, a player is not required to try to learn from the past, even if doing so could refine his beliefs about the opponents' unobserved past, present and future moves.

In a sense, the forward induction concept of extensive-form rationalizability (Pearce (1984), Battigalli (1997)) takes the other extreme by excluding, whenever possible, mistakes in the execution of planned strategies. However, to make this possible, a player may need to ascribe beliefs to the opponents that assume only a limited degree of rationality of their respective opponents. This, in turn, may lead to counterintuitive predicted behavior after surprises. The example in Figure 1, which is a variant of Figure 3 in Reny (1992), will illustrate this.

Upon reaching $h_{2}$, player 2 is forced to believe that player 1 chooses strategy $(b, f)$, as this is the only way for player 1 to get at least 5 - a payoff he could guarantee by choosing $a$. At the same time, player 2 must believe that player 1 ascribes a high probability to player 2 behaving irrationally at $h_{4}$. The unique best reply for player 2 is to choose strategy $(d, g)$. However, if player 1 in fact believes that player 2 will choose rationally at $h_{4}$, and chooses rationally himself in the remainder of the game, then player 1 would

[^1]choose $e$ at $h_{3}$, yielding an extremely low payoff for player 2 .
We find the prediction $(d, g)$ for player 2 unsatisfactory, because signs of irrationality by an opponent in the past - even if it is only by him ascribing low levels of rationality to the other players, and choosing optimally upon it - does not necessarily mean that this opponent will continue to do so in the future. Indeed, in the example above, how can player 2 be sure that player 1 will not "wake up" at $h_{3}$, but rather continue to hold the unreasonable belief that player 2 will choose irrationally at $h_{4}$ ? It could as well be that player 1 held a reasonable belief about player 2 from the beginning, but chose $b$ by mistake. As any good chess player knows, past mistakes by an opponent do not guarantee that he will make any mistakes in the future. In this sense, it is very dangerous to draw too strong conclusions from the opponents' past irrational behavior. But this is precisely what extensive-form rationalizability does in many instances. As such, this concept is not robust with respect to players increasing their confidence in the opponents' future rationality after observing surprising moves.

Overall, we thus see some shortcomings with both backward and forward induction reasoning as discussed above. In response, we propose a rationalizability concept for dynamic games - different from both extensive-form rationalizability and pure backward induction reasoning - which we call forward and backward rationalizability. In this new concept, we require players to learn from the past, but only as much as is consistent with "fully rational behavior" in the future.

More formally, the concept proceeds by applying the forward induction concept of extensive-form rationalizability in a backward inductive fashion: We start by applying extensive-form rationalizability to the last period in the game, which results in restrictions on strategies and beliefs there. Taking these restrictions as given, we then apply the extensive-form rationalizability procedure to the parts of the game that start at the penultimate period, and so on, until we reach the beginning of the game.

We then ask: What does the new concept of forward and backward rationalizability entail in terms of reasoning? The epistemic characterization of extensive-form rationalizability as given by Battigalli and Siniscalchi (2002) relies on strong belief in rationality, which means that a player, whenever possible, should believe that his opponents are choosing rationally in the whole game. On top of this, Battigalli and Siniscalchi (2002) require that a player must also believe, whenever possible, that his opponents choose rationally in the whole game while strongly believing in the other players' rationality. Iterating this argument leads to rationality and common strong belief in rationality - a set of epistemic conditions for which Battigalli and Siniscalchi (2002) show that they characterize extensive-form rationalizability.

Recall that our concept imposes extensive-form rationalizability from any period onwards in a backward inductive fashion, starting at the last period and then working backwards towards the first period. It is shown in Theorem 4.1 that our concept can be characterized epistemically by (a) first imposing common strong belief in rationality from the last period onwards, (b) then imposing common strong belief in rationality from the penultimate period onwards, keeping the restrictions from (a), and so on, until we reach the beginning of the game.

As a consequence, when a player finds himself at an information set $h$, then he looks for the earliest period $m$ before $h$ such that some iterations of strong belief in rationality from period $m$ onwards can explain the event of reaching $h$. In this case, the player will believe that common strong belief in rationality from period $m+1$ onwards will hold. This yields a best rationalization principle for the new concept. In

Figure 2: Battle of the sexes with double outside option
particular, even at information sets a player did not expect to be reached, this player will always ascribe the highest possible degree of rationality, from this information set onwards, to his opponents.

Intuitively, the reasoning process of a player choosing forward and backward rationalizable strategies can thus be described as follows: "Yesterday I believed that my opponents are rational from then (yesterday) on, believed that everybody else believed that everybody (else) is rational from then on, and so forth. If this is not falsified by today's observations, I should continue to believe not only that everybody else is rational from today on, and so forth, but also that everybody else was rational from yesterday on, and so forth. The same applies to the day before yesterday, the day before that, and so on."

The concept of forward and backward rationalizability can also be restricted to the part of the game that starts at a certain period, say period $m$. We would thus obtain a bounded rationality variant of the concept, where players do not actively reason about choices that were taken before period $m$. Our epistemic characterization can also be used to see what reasoning is required to arrive at such a bounded rationality version of the concept.

We next investigate how the new concept relates to existing concepts, such as extensive-form rationalizability and backwards rationalizability. In the example of Figure 1, for instance, the new concept coincides with backward induction. However, there are other games where the concept is different, in terms of strategies, from both pure backward induction reasoning and extensive-form rationalizability. Consider, for instance, the game in Figure 2.

Extensive-form rationalizability would reason as follows: At $h_{2}$, player 2 must believe that player 1 chooses strategy $(a, e)$, as this is the only strategy reaching $h_{2}$ that would yield player 1 at least $2-\mathrm{a}$ payoff he could guarantee by choosing $b$ at the beginning. But then, player 2 would choose $d$, and player 1 , anticipating this, would choose $b$.

Our concept of forward and backward rationalizability proceeds differently: In the last subgame, at $h_{3}$, it imposes no restrictions. Now consider the subgame starting at $h_{2}$, which is the classical Battle of the Sexes game with an outside option for player 2. Our concept uniquely selects the forward induction strategies $(c, h)$ and $f$ in this subgame. Finally, we turn to the whole game. Given the earlier restrictions, player 1 must believe that player 2 will choose $(c, h)$, and therefore will choose $b$ himself. In particular, it predicts that player 2 will choose ( $c, h$ ) and not $d$, as extensive-form rationalizability predicts.

Our new concept thus yields a different strategy for player 2 than extensive-form rationalizability, but it induces the same outcome - player 1 choosing $b$ at the beginning. In Theorem 6.3 we show that this is no coincidence: The two concepts will always yield the same outcomes, but may differ in terms of strategies.

When compared to the pure backward induction concept of backwards rationalizability, our concept of forward and backward rationalizability always yields a refinement of the latter - not only in terms of outcomes but also in terms of strategies. See Theorem 5.1. In the game of Figure 2, for instance, backwards rationalizability yields the same strategies for player 1 as our concept, which is only strategy $b$, but allows for strategies $(c, h)$ and $d$ for player 2 whereas our concept only allows for $(c, h)$. In fact, the new concept of forward and backward rationalizability can be viewed as a backward looking strengthening of the purely forward looking concept of backwards rationalizability: On top of always believing that the opponent will choose rationally in the future, which is what backwards rationalizability entails, we require a player to also explain (some of) the opponent's past choices whenever possible. In particular, after observing a surprising move by an opponent, the new concept requires the player to always reason in accordance with common belief in future rationality (Perea (2014)), and thus to assign the highest possible degree of future rationality to the opponent.

Although our concept is equivalent to extensive-form rationalizability in terms of outcomes, we believe that strategies matter. Surprises and mistakes do happen regularly in reality, and therefore we find it important to critically analyze how players react to surprises. Indeed, a satisfactory theory of rational behavior should also describe how rational players act and reason upon observing surprising, or even irrational, behavior by their opponents. As we have argued in Figure 1, we think that extensive-form rationalizability does not provide an appealing theory for how players react to such surprises. Different from extensive-form rationalizability, under the concept of forward and backward rationalizability a player will never believe that an opponent will choose irrationally in the future, nor will a player attribute an unreasonable belief to an opponent. In that sense, we believe that the new concept provides a more satisfactory theory for how players react to surprises, and that it offers an alternative plausible rationale for extensive-form rationalizable outcomes.

An important immediate consequence of the two results mentioned above is that in every dynamic game with imperfect information, every extensive-form rationalizable outcome is also induced by some profile of backwards rationalizable strategies. Catonini (2020) and Perea (2017) have already proven this result for dynamic games with observed past choices, but we show that this property even holds for games with imperfectly observed past choices. This may be viewed as a generalization of Battigalli's theorem, which states that in every dynamic game with perfect information and without relevant ties, the unique extensiveform rationalizable outcome is the backward induction outcome.

We finally investigate how players reason if they learn that the game was actually preceded by some
earlier moves they were initially unaware of. Traditionally, we analyze a game by assuming that all players know that this is the game being played, and we may be interested in the players' behavior at "surprising" subgames, which were initially not expected to be reached. But instead of assuming that a player finds himself in a "surprising" subgame, it may also happen that a player initially views this subgame as the "whole game", and then learns that this game was actually preceded by some past moves. ${ }^{2}$ If this happens then this could be a reason for the player to refine his reasoning but, so we argue, it should never be a reason to completely overthrow the reasoning he did before. After all, the player reasoned himself towards a set of possible beliefs and strategies based on the accurate description of the game from now on, and the fact that the game actually started earlier does not change the accuracy of this description. If the game was in fact preceded by some past moves, this additional information should only lead to sharper predictions, but not to new beliefs and strategies which were considered irrational before receiving this new piece of information. Indeed, it is always possible that the moves preceding the game were chosen by mistake. This principle, that new information about past moves should only lead players to refine their reasoning, but not to overthrow their reasoning, is called supergame monotonicity.

As is easily seen, the game of Figure 1 shows that extensive-form rationalizability violates this basic principle. If the game were to start at $h_{2}$, then extensive-form rationalizability would uniquely select the strategy $c$ for player 2. However, if player 2 learns that the game in fact started at $h_{1}$, then extensive-form rationalizability would uniquely select strategy $(d, g)$ for player 2 , and therefore the previous reasoning of player 2 would be completely overthrown by this new information.

In contrast, the pure backward induction concept of backwards rationalizability trivially satisfies supergame monotonicity, as the reasoning of a player remains unaffected if he learns that the game was preceded by earlier moves. Thus, supergame monotonicity holds with equality in this case, because players completely discard the additional information provided by past moves.

We show in Theorem 8.1 that the new concept of forward and backward rationalizability always satisfies supergame monotonicity, and it does so in a non-trivial way for many games. Consider, for instance, the game from Figure 2. If the game were to start at $h_{3}$, our concept selects both $e$ and $f$ for player 1. However, if player 1 learns that the game started at $h_{2}$, this additional information will refine the set of possible choices for player 1 to only $f$.

The paper is organized as follows: In Section 2 we lay out the basic definitions and notation for dynamic games. In Section 3 we formally define the extensive-form rationalizability procedure, the backwards rationalizability procedure and the new forward and backward rationalizability procedure. In Section 4 we provide an epistemic characterization of our concept. In Section 5 we show that the new concept constitutes a refinement, in terms of strategies, of backwards rationalizability, whereas we prove in Section 6 that in terms of outcomes it is equivalent to extensive-form rationalizabity. In Section 7 we show how these results imply a generalization of Battigalli's theorem, by proving that in every dynamic game with possibly imperfect information, all extensive-form rationalizable outcomes are also backwards rationalizable. In Section 8 we discuss the principle of supergame monotonicity. The appendix contains all the proofs.

[^2]
## 2 Preliminaries

In this section we introduce our model of dynamic games and establish the notation we use. Subsequently, we define strategies, conditional belief vectors, strong belief, and optimal choice at information sets.

### 2.1 Dynamic Games

In this paper we consider finite dynamic games that allow for simultaneous moves and imperfect information, and where every action and history can be indexed by time. Formally, a dynamic game is a tuple $\Gamma=$ $\left(I, T,\left(P^{m}\right)_{m \in T}, I^{a},\left(A_{i}, H_{i}\right)_{i \in I}, Z,\left(u_{i}\right)_{i \in I}\right)$, where
(a) $I$ is the finite set of players;
(b) $T=\{L, L+1, \ldots, M+1\}$ is the collection of time periods, with $L, M \in \mathbf{Z}$ and $L \leq M$. The reason we allow the first time period to be different from 1 is that later we look at subgames and supergames of $\Gamma$, which are games by themselves and may start at a later or earlier time period;
(c) for every period $m \in T$ we denote by $P^{m}$ the set of past action profiles, or histories, at period $m$, to be defined below. By $P:=\cup_{m \in T} P^{m}$ we denote the set of all possible histories;
(d) the mapping $I^{a}$ assigns to every history $p \in P$ the set of active players $I^{a}(p) \subseteq I$ who must choose after history $p$. If $I^{a}(p)$ contains more than one player, there are simultaneous moves after $p$. We also allow $I^{a}(p)$ to be empty, in which case no player chooses after history $p$. In this case, $p$ will be a terminal history. By $P_{i}$ we denote the set of histories $p \in P$ with $i \in I^{a}(p)$;
(e) for every player $i$, the mapping $A_{i}$ assigns to every history $p \in P_{i}$ the finite set of actions $A_{i}(p)$ from which player $i$ can choose after history $p$;
(f) for every period $m \in T$, the set $P^{m}$ of histories at period $m$ is inductively defined by $P^{L}:=\left\{p^{L}\right\}$, and

$$
P^{m}:=\left\{\left(p^{m-1},\left(a_{i}\right)_{i \in I^{a}\left(p^{m-1}\right)}\right) \mid p^{m-1} \in P^{m-1} \text { and } a_{i} \in A_{i}\left(p^{m-1}\right) \text { for all } i \in I^{a}\left(p^{m-1}\right)\right\}
$$

for every $m \in\{L+1, \ldots, M+1\}$. That is, a history in $P^{m}$ describes which actions have been chosen before period $m$. We assume that $I^{a}(p)=\emptyset$ for every history $p \in P^{M+1}$. That is, every history in the last period $M+1$ will be a terminal history. We say that a history $p$ precedes a history $p^{\prime}$ (or, $p^{\prime}$ follows $p$ ) if $p^{\prime}$ results by adding some actions after $p$;
(g) for every player $i$, the mapping $H_{i}$ assigns to every period $m \in\{L, \ldots, M\}$ a partition $H_{i}^{m}=$ $\left\{h_{i}^{m .1}, \ldots, h_{i}^{m . K_{i m}}\right\}$ of the set of histories $P_{i} \cap P^{m}$ into information sets. The interpretation is that for every information set $h \in H_{i}^{m}$, player $i$ cannot distinguish between any two histories $p, p^{\prime} \in h$. However, the player always knows in which time period he is. By $H_{i}:=\cup_{m \in T} H_{i}^{m}$ we denote the collection of information sets for player $i$, whereas $H:=\cup_{i \in I} H_{i}$ denotes the collection of all information sets of all players. For a given period $m$, we denote by $H^{m}:=\cup_{i \in I} H_{i}^{m}$ the collection of all information sets at period $m$. As player $i$ 's set of actions must be the same for every two histories between which he cannot distinguish, we require, for every player $i$, and every information set $h \in H_{i}$, that $A_{i}(p)=A_{i}\left(p^{\prime}\right)$ for every $p, p^{\prime} \in h$. By $A_{i}(h)$ we denote the unique set of actions between which player $i$ can choose at information set $h \in H_{i}$. We require that $A_{i}(h) \cap A_{i}\left(h^{\prime}\right)=\emptyset$ for every two distinct information sets $h, h^{\prime} \in H_{i}$. We also assume perfect recall, which means that player $i$ always remembers which actions he chose in the past, and which information he
had about the opponents' past actions at previous periods. Formally, for every player $i$, every information set $h \in H_{i}$, and every two histories $p, p^{\prime} \in H_{i}$, the set of player $i$ actions in $p$ and $p^{\prime}$ must be the same (and consequently, the collection of player $i$ information sets that $p$ and $p^{\prime}$ cross must be the same). For every two information sets $h, h^{\prime} \in H$, we say that $h$ precedes $h^{\prime}$ (or $h^{\prime}$ follows $h$ ) if there is a history $p \in h$ and a history $p^{\prime} \in h^{\prime}$ such that $p$ precedes $p^{\prime}$;
(h) $Z$ is the set of terminal histories given by

$$
Z:=\left\{p \in P \mid I^{a}(p)=\emptyset\right\} .
$$

These are thus the histories after which no player makes a move. As such, a terminal history $z \in Z$ describes which actions have been chosen from the beginning to the end;
(i) for every player $i$, the utility function $u_{i}: Z \rightarrow \mathbf{R}$ assigns to every terminal history $z \in Z$ some utility $u_{i}(z)$.

### 2.2 Strategies

A strategy for player $i$ assigns an available action to every information set at which player $i$ is active, and that is not excluded by earlier actions in the strategy. Formally, let $\tilde{s}_{i}$ be a mapping that assigns to every information set $h \in H_{i}$ some action $\tilde{s}_{i}(h) \in A_{i}(h)$. We call $\tilde{s}_{i}$ a complete strategy. Then, a history $p \in P$ is excluded by $\tilde{s}_{i}$ if there is some information set $h \in H_{i}$, with some history $p^{\prime} \in h$ preceding $p$, such that $\tilde{s}_{i}(h)$ is different from the unique player $i$ action at $p^{\prime}$ leading to $p$. An information set $h \in H$ is excluded by $\tilde{s}_{i}$ if all histories in $h$ are excluded by $\tilde{s}_{i}$. The strategy induced by $\tilde{s}_{i}$ is the restriction of $\tilde{s}_{i}$ to those information sets in $H_{i}$ that are not excluded by $\tilde{s}_{i}$. A mapping $s_{i}: \tilde{H}_{i} \rightarrow \cup_{h \in \tilde{H}_{i}} A_{i}(h)$, where $\tilde{H}_{i} \subseteq H_{i}$, is a strategy for player $i$ if it is the strategy induced by a complete strategy ${ }^{3}$. By $S_{i}$ we denote the set of strategies for player $i$, and by $S_{-i}:=\times_{j \neq i} S_{j}$ the set of strategy combinations for $i$ 's opponents.

Consider a strategy profile $s=\left(s_{i}\right)_{i \in I}$ in $\times_{i \in I} S_{i}$. Then, $s$ induces a unique terminal history $z(s)$. We say that the strategy profile $s$ reaches a history $p$ if $p$ precedes $z(s)$. Similarly, the strategy profile $s$ is said to reach an information set $h$ if $s$ reaches a history in $h$.

For a given player $i$ and information set $h \in H_{i}$, we define the sets

$$
\begin{aligned}
S(h) & :=\left\{s \in \times_{i \in I} S_{i} \mid s \text { reaches } h\right\}, \\
S_{i}(h) & :=\left\{s_{i} \in S_{i} \mid \text { there is some } s_{-i} \in S_{-i} \text { such that }\left(s_{i}, s_{-i}\right) \in S(h)\right\}, \text { and } \\
S_{-i}(h) & :=\left\{s_{-i} \in S_{-i} \mid \text { there is some } s_{i} \in S_{i} \text { such that }\left(s_{i}, s_{-i}\right) \in S(h)\right\} .
\end{aligned}
$$

Intuively, $S_{i}(h)$ is the set of strategies for player $i$ that allow for information set $h$ to be reached, whereas $S_{-i}(h)$ is the set of opponents' strategy combinations that allow for $h$ to be reached. By perfect recall it holds, for every player $i$ and every information set $h \in H_{i}$, that $S(h)=S_{i}(h) \times S_{-i}(h)$. For a given strategy $s_{i} \in S_{i}$, we denote by $H_{i}\left(s_{i}\right):=\left\{h \in H_{i} \mid s_{i} \in S_{i}(h)\right\}$ the collection of information sets for player $i$ that the strategy $s_{i}$ allows to be reached.

[^3]
### 2.3 Conditional Belief Vectors and Strong Belief

For a finite set $X$, let $\Delta(X)$ be the set of probability distributions on $X$. A conditional belief vector for player $i$ is a mapping $b_{i}$ that assigns to every information set $h \in H_{i}$ a probabilistic belief $b_{i}(h) \in \Delta\left(S_{-i}(h)\right)$ about the opponents' strategy combinations that allow for $h$ to be reached. Moreover, a conditional belief vector $b_{i}$ is required to satisfy Bayesian updating whenever possible. That is, for every $h, h^{\prime} \in H_{i}$ where $h$ precedes $h^{\prime}$ and $b_{i}(h)\left(S_{-i}\left(h^{\prime}\right)\right)>0$ we have that

$$
b_{i}\left(h^{\prime}\right)\left(s_{-i}\right)=\frac{b_{i}(h)\left(s_{-i}\right)}{b_{i}(h)\left(S_{-i}\left(h^{\prime}\right)\right)}
$$

for every $s_{-i} \in S_{-i}\left(h^{\prime}\right) .{ }^{4}$ Let $B_{i}$ be the set of all conditional belief vectors for player $i$ that satisfy Bayesian updating whenever possible.

For a given player $i$, consider a set of opponents' strategy combinations $D_{-i} \subseteq S_{-i}$. Say that a conditional belief vector $b_{i} \in B_{i}$ strongly believes $D_{-i}$ if for every information set $h \in H_{i}$ with $S_{-i}(h) \cap D_{-i} \neq \emptyset$ we have that $b_{i}(h)\left(D_{-i}\right)=1$. That is, $b_{i}$ assigns full probability to strategy combinations in $D_{-i}$ whenever this is possible.

### 2.4 Optimal Choice at Information Sets

Recall that every strategy combination $s=\left(s_{i}\right)_{i \in I}$ induces a terminal history $z(s)$. For a strategy $s_{i}$, an information set $h \in H_{i}\left(s_{i}\right)$ and a conditional belief vector $b_{i}$, let

$$
u_{i}\left(s_{i}, b_{i}(h)\right):=\sum_{s_{-i} \in S_{-i}(h)} b_{i}(h)\left(s_{-i}\right) \cdot u_{i}\left(z\left(s_{i}, s_{-i}\right)\right)
$$

be the expected utility induced by strategy $s_{i}$ at information $h$ under the conditional belief vector $b_{i}$. A strategy $s_{i}$ is optimal for $b_{i}$ at $h \in H_{i}\left(s_{i}\right)$ if

$$
u_{i}\left(s_{i}, b_{i}(h)\right) \geq u_{i}\left(s_{i}^{\prime}, b_{i}(h)\right) \text { for all } s_{i}^{\prime} \in S_{i}(h) .
$$

For a given time period $m$, strategy $s_{i}$ is said to be optimal for $b_{i}$ from period $m$ onwards if for every period $\tau \geq m$ and every information set $h \in H_{i}\left(s_{i}\right) \cap H_{i}^{\tau}$, strategy $s_{i}$ is optimal for $b_{i}$ at $h$.

Note that if a strategy $s_{i}$ does not allow any information set in $H^{\tau}$ with $\tau \geq m$ to be reached then, by definition, $s_{i}$ is (vacuously) optimal from period $m$ onwards for every $b_{i} \in B_{i}$. It can be shown that the following is true:

Remark 2.1 For every conditional belief vector $b_{i} \in B_{i}$, every period $m \in\{L, \ldots, M\}$ and every information set $h \in H^{m}$, there is a strategy $s_{i}$ that allows $h$ to be reached and that is optimal for $b_{i}$ from period $m$ onwards.

[^4]
## 3 Definition of the Concepts

In this section we formally introduce the concepts of extensive-form rationalizability, backwards rationalizability and the new concept of forward and backward rationalizability.

### 3.1 Extensive-Form Rationalizability

The extensive-form rationalizability procedure (Pearce (1984), Battigalli (1997)) is a forward induction procedure that recursively eliminates strategies and conditional belief vectors for every player. The main idea is that a player, whenever possible, must believe that his opponents are implementing strategies that are optimal from the beginning (that is, from period $L$ onwards). On top of this, a player must also believe, whenever possible, that his opponents are not only implementing strategies that are optimal from the beginning, but also that the opponents engage in the reasoning described above. Iterating these reasoning steps then leads to extensive-form rationalizability.

Definition 3.1 (Extensive-form rationalizability) Round 0: For every player $i$, set $B_{i}^{0}:=B_{i}$ and $S_{i}^{0}:=S_{i}$.
Round $k \geq 1$ : For every player $i$, set

$$
B_{i}^{k}:=\left\{b_{i} \in B_{i}^{k-1} \mid b_{i} \text { strongly believes } S_{-i}^{k-1}\right\}
$$

and

$$
S_{i}^{k}:=\left\{s_{i} \in S_{i}^{k-1} \mid s_{i} \text { optimal for some } b_{i} \in B_{i}^{k} \text { from period } L \text { onwards }\right\} .
$$

Strategy $s_{i} \in S_{i}$ is extensive-form rationalizable if $s_{i} \in S_{i}^{k}$ for all $k \geq 0$. Conditional belief vector $b_{i}$ is extensive-form rationalizable if $b_{i} \in B_{i}^{k}$ for all $k \geq 0$.

We will see that the new concept of forward and backward rationalizability applies the extensive-form rationalizability procedure in a backward inductive fashion.

### 3.2 Backwards Rationalizability

The concept of backwards rationalizability (Perea (2014), Penta (2015)) is purely forward looking, and can thus be viewed as a genuine backward induction concept. This can also be seen from the fact that the resulting strategies can be characterized by common belief in future rationality (Perea (2014)), stating that a player always believes that his opponents will choose rationally now and in the future, always believes that his opponents always believe that the other players will choose rationally now and in the future, and so on.

Definition 3.2 (Backwards rationalizability) Consider a dynamic game with time periods $L, \ldots, M+1$.

Period $M$, round 0. Set $S_{i}^{M .0}:=S_{i}$ and $B_{i}^{M .0}:=B_{i}$ for all players $i$.
Period $M$, round $k \geq 1$. For every player $i$, set

$$
B_{i}^{M . k}:=\left\{b_{i} \in B_{i}^{M . k-1} \mid b_{i}(h)\left(S_{-i}^{M . k-1}\right)=1 \text { for all } h \in H_{i}^{M}\right\},
$$

and

$$
S_{i}^{M . k}:=\left\{s_{i} \in S_{i}^{M . k-1} \mid s_{i} \text { optimal for some } b_{i} \in B_{i}^{M . k} \text { from period } M \text { onwards }\right\} .
$$

Continue until $B_{i}^{M . K_{M}}=B_{i}^{M . K_{M}+1}$ and $S_{i}^{M . K_{M}}=S_{i}^{M . K_{M}+1}$ for some round $K_{M}$, and for all players $i$.
Period $m \leq M-1$, round 0 . Set $S_{i}^{m .0}:=S_{i}^{m+1 \cdot K_{m+1}}$ and $B_{i}^{m .0}:=B_{i}^{m+1 \cdot K_{m+1}}$ for all players $i$.
Period $m \leq M-1$, round $k \geq 1$. For every player $i$, let

$$
B_{i}^{m \cdot k}:=\left\{b_{i} \in B_{i}^{m \cdot k-1} \mid b_{i}(h)\left(S_{-i}^{m \cdot k-1}\right)=1 \text { for all } h \in H_{i}^{m}\right\},
$$

and

$$
S_{i}^{m . k}:=\left\{s_{i} \in S_{i}^{m . k-1} \mid s_{i} \text { optimal for some } b_{i} \in B_{i}^{m . k} \text { from period } m \text { onwards }\right\} .
$$

Continue until $B_{i}^{m \cdot K_{m}}=B_{i}^{m \cdot K_{m}+1}$ and $S_{i}^{m \cdot K_{m}}=S_{i}^{m \cdot K_{m}+1}$ for some round $K_{m}$, and for all players $i$.
A strategy $s_{i}$ is backwards rationalizable if $s_{i} \in S_{i}^{L . K_{L}}$, and a conditional belief vector $b_{i}$ is backwards rationalizable if $b_{i} \in B_{i}^{L . K_{L}}$.

The definition we have provided here uses the backwards order of elimination. That is, we start by eliminating at the ultimate period, subsequently we do the eliminations at the penultimate period, and so on, until we reach the beginning of the game. Perea (2014)'s definition is different, as in every round it (potentially) performs eliminations at each of the information sets in each of the periods. However, it is argued in Section 6.3 of Perea (2014) that the definition we provide here is equivalent, in terms of strategies and conditional belief vectors selected, to the definition in Perea (2014).

### 3.3 Forward and Backward Rationalizability

The new concept of forward and backward rationalizability combines elements from the extensive-form rationalizability procedure and the backwards rationalizability procedure. Like the backwards rationalizability procedure, it proceeds in a backward inductive fashion by first performing eliminations at the ultimate period, and then proceeding backwards until we reach the beginning of the game. However, when we reach a certain period $m$ in this way then, in line with extensive-form rationalizability, we also require players at later periods to reason about the opponents' past moves at period $m$. This is fundamentally different from backwards rationalizability, where players at a given period are only required to reason about the opponents' moves at this period and future periods.

Definition 3.3 (Forward and backward rationalizability) Consider a dynamic game with time periods $L, \ldots, M+1$.

Period $M$, round 0 . Set $S_{i}^{M .0}:=S_{i}$ and $B_{i}^{M .0}:=B_{i}$ for all players $i$.
Period $M$, round $k \geq 1$. For every player $i$, set

$$
B_{i}^{M . k}:=\left\{b_{i} \in B_{i}^{M . k-1} \mid b_{i} \text { strongly believes } S_{-i}^{M . k-1}\right\},
$$

and

$$
S_{i}^{M . k}:=\left\{s_{i} \in S_{i}^{M . k-1} \mid s_{i} \text { optimal for some } b_{i} \in B_{i}^{M . k} \text { from period } M \text { onwards }\right\} .
$$

Continue until $B_{i}^{M . K_{M}}=B_{i}^{M . K_{M}+1}$ and $S_{i}^{M . K_{M}}=S_{i}^{M \cdot K_{M}+1}$ for some round $K_{M}$, and for all players $i$.
Period $m \leq M-1$, round 0 . Set $S_{i}^{m .0}:=S_{i}^{m+1 \cdot K_{m+1}}$ and $B_{i}^{m .0}:=B_{i}^{m+1 \cdot K_{m+1}}$ for all players $i$.
Period $m \leq M-1$, round $k \geq 1$. For every player $i$, let

$$
B_{i}^{m . k}:=\left\{b_{i} \in B_{i}^{m . k-1} \mid b_{i} \text { strongly believes } S_{-i}^{m . k-1}\right\},
$$

and

$$
S_{i}^{m . k}:=\left\{s_{i} \in S_{i}^{m . k-1} \mid s_{i} \text { optimal for some } b_{i} \in B_{i}^{m . k} \text { from period } m \text { onwards }\right\} .
$$

Continue until $B_{i}^{m \cdot K_{m}}=B_{i}^{m \cdot K_{m}+1}$ and $S_{i}^{m \cdot K_{m}}=S_{i}^{m \cdot K_{m}+1}$ for some round $K_{m}$, and for all players $i$.
A strategy $s_{i}$ is forward and backward rationalizable if $s_{i} \in S_{i}^{L . K_{L}}$, and a conditional belief vector $b_{i}$ is forward and backward rationalizable if $b_{i} \in B_{i}^{L \cdot K_{L}}$.

In the initial step we thus apply the extensive-form rationalizability procedure to those parts of the game that start at the final decision period $M$, where every player makes at most one choice. In the next step, we turn to the parts of the game that start at period $M-1$, and apply the extensive-form rationalizability procedure there, taking as an input the restrictions from the initial step. The transition from period $m$ to $m-1$ works in an analogous way, by taking as input the restrictions from period $m$. We continue in this fashion until we reach the beginning of the game. Hence, we apply the extensive-form rationalizability procedure in a backward inductive fashion.

For a given player $i$ and information set $h$ in period $m$, let $\tau \leq m$ be the earliest period such that $S_{i}^{\tau \cdot k} \cap S_{i}(h) \neq \emptyset$ for some round $k \geq 0$. For this period $\tau$, let $l$ be the highest such round with $S_{i}^{\tau \cdot l} \cap S_{i}(h) \neq \emptyset .{ }^{5}$ Then, we denote by $S_{i}^{f b r}(h):=S_{i}^{\tau \cdot l} \cap S_{i}(h)$ the set of strategies that is predicted conditional on reaching information set $h$.

Note that according to our concept, a player $j \neq i$ with $h \in H_{j}$ may believe at information set $h$ that player $i$ chooses a strategy which is not in $S_{i}^{f b r}(h)$ in case there are more than two players. Indeed, it may be that $S_{i}^{f b r}(h)=S_{i}^{\tau \cdot l} \cap S_{i}(h)$, whereas for a third player $n \neq i, j$ we have that $S_{n}^{f b r}(h)=S_{n}^{\tau^{\prime} \cdot l^{\prime}} \cap S_{n}(h)$, where either $\tau^{\prime}>\tau$ or $\left(\tau^{\prime}=\tau\right.$ and $\left.l^{\prime}<l\right)$. In that case, a conditional belief vector $b_{j}$ that is forward and

[^5]backward rationalizable may at $h$ assign positive probability to opponents' strategy combinations containing some $s_{i} \in S_{i}^{\tau^{\prime} . l^{\prime}} \backslash S_{i}^{\tau . l}$.

By construction, our procedure will refine the conditional beliefs of player $i$ at some information set $h \in H_{i}^{m}$ until we reach a period $\tau<m$ where $S_{-i}^{\tau . k} \cap S_{-i}(h)$ becomes empty for some $k \geq 1$. In that case, player $i$ 's conditional beliefs at $h$ will thus be anchored at period $\tau$ and round $k-1$. This implies that at $h$, player $i$ believes that his opponents were "level $(k-1)$-rational" from period $\tau$ onwards, and "fully rational" from period $\tau+1$ onwards.

It is not difficult to prove that the concept always yields at least one strategy and conditional belief vector for every player.

Theorem 3.1 (Existence) For every player there are always at least one strategy and one conditional belief vector that are forward and backward rationalizable.

Thus, it can never happen that all remaining strategies or conditional belief vectors for a given player are eliminated at a particular round.

### 3.4 Examples

We will now illustrate the forward and backward rationalizability procedure by means of two examples.
Example 1. Consider first the example from Figure 2 in the introduction. There are four time periods in this game: Period 1 with information set $h_{1}$, period 2 with information set $h_{2}$, period 3 with information set $h_{3}$, and period 4 where the game ends. That is, $L=1$ and $M=3$. We will now run the forward and backward rationalizability procedure, starting at period 3 .
Period 3. We have that $B_{1}^{3.1}=B_{1}$ and $B_{2}^{3.1}=B_{2}$. For player 1 , both strategies $(a, e)$ and $(a, f)$ are optimal from period 3 onwards for some conditional belief vector in $B_{1}^{3.1}$, and similarly for player 2 's strategies $(c, g)$ and $(c, h)$. Note that the strategies $b$ and $d$ are vacuously optimal from period 3 onwards for some conditional belief vector in $B_{1}^{3.1}$ and $B_{2}^{3.1}$, respectively. Thus,

$$
S_{1}^{3.1}=S_{1}=\{b,(a, e),(a, f)\} \text { and } S_{2}^{3.1}=S_{2}=\{d,(c, g),(c, h)\}
$$

and this is where the procedure at Period 3 terminates.
Period 2. Round 1. We have that $B_{1}^{2.1}=B_{1}$ and $B_{2}^{2.1}=B_{2}$. For player 2, strategy $(c, g)$ is not optimal from period 2 onwards for any conditional belief vector in $B_{2}^{2.1}$. In turn, strategies $(c, h)$ and $d$ are optimal from period 2 onwards for some conditional belief vector in $B_{2}^{2.1}$. Thus,

$$
S_{2}^{2.1}=\{d,(c, h)\}
$$

Round 2. We then have

$$
B_{1}^{2.2}=\left\{b_{1} \in B_{1} \mid b_{1}\left(h_{1}\right)(\{d,(c, h)\})=1 \text { and } b_{1}\left(h_{3}\right)((c, h))=1\right\}
$$

Since for player 1 only strategies $b$ and $(a, f)$ are optimal from period 2 onwards for some conditional belief vector in $B_{1}^{2.2}$, it follows that

$$
S_{1}^{2.2}=\{b,(a, f)\}
$$

Round 3. This implies that

$$
B_{2}^{2.3}=\left\{b_{2} \in B_{2} \mid b_{2}\left(h_{2}\right)((a, f))=1 \text { and } b_{2}\left(h_{3}\right)((a, f))=1\right\} .
$$

For player 2 , only strategy $(c, h)$ is optimal from period 2 onwards for some conditional belief vector in $B_{2}^{2.3}$, and we thus conclude that

$$
S_{2}^{2.3}=\{(c, h)\}
$$

Round 4. We then have that

$$
B_{1}^{2.4}=\left\{b_{1} \in B_{1} \mid b_{1}\left(h_{1}\right)((c, h))=1 \text { and } b_{1}\left(h_{3}\right)((c, h))=1\right\}
$$

after which no further eliminations are possible in period 2 .
Period 1. We start with the restrictions on the strategies and conditional belief vectors inherited from period 2. That is,

$$
\begin{aligned}
S_{1}^{1.0}=\{b,(a, f)\}, B_{1}^{1.0} & =\left\{b_{1} \in B_{1} \mid b_{1}\left(h_{1}\right)((c, h))=1 \text { and } b_{1}\left(h_{3}\right)((c, h))=1\right\} \\
S_{2}^{1.0}=\{(c, h)\} \text { and } B_{2}^{1.0} & =\left\{b_{2} \in B_{2} \mid b_{2}\left(h_{2}\right)((a, f))=1 \text { and } b_{2}\left(h_{3}\right)((a, f))=1\right\} .
\end{aligned}
$$

For player 1, the only strategy that is optimal from period 1 onwards for some conditional belief vector in $B_{1}^{1.0}$ is $b$. We therefore have

$$
S_{1}^{1.1}=\{b\} .
$$

Afterwards, no further eliminations are possible. We thus conclude that the strategies selected by the forward and backward rationalizability procedure are $b$ for player 1 and $(c, h)$ for player 2.

On the other hand, as we have seen in the introduction, extensive-form rationalizability selects the strategies $b$ for player 1 and $d$ for player 2. The intuition for this difference is the following: According to forward and backward rationalizability, player 2 asks at $h_{2}$ : What is the earliest period $m$ such that player 1's past behavior - that is, player 1 choosing $a$ - can be explained by "full rationality" from period $m$ onwards? This must be period 2. Indeed, from period 2 onwards, player 1 expects player 2 to choose $(c, h)$, which makes it optimal for player 1 , from period 2 onwards, to choose $(a, f)$. In turn, if player 2 expects player 1 to choose $(a, f)$, then it is optimal for player 2 to choose $(c, h)$. This is a plausible theory for the reasoning and play from period 2 onwards.

However, if player 1 anticipates player 2 choosing $(c, h)$, then it can never be optimal for player 1 to choose $a$ at $h_{1}$. As such, player 1 choosing $a$ cannot be explained by "full rationality" from period 1 onwards.

According to extensive-form rationalizability, player 2 asks at $h_{2}$ : Is there a strategy for player 1 involving his observed past move $a$ that is optimal for some belief, even if this belief attributes irrational future strategies to player 2? This reasoning leads player 2 to believe that player 1 chooses $(a, e)$, as this is the

Figure 3: A dynamic game with non-trivial information sets
only strategy involving $a$ that can possibly yield him at least 2 . As a consequence, player 2 will choose $d$. Note, however, that stratey $(a, e)$ can only yield player 1 at least 2 if he believes that player 2 irrationally chooses the strategy $(c, g)$ in the future. As such, believing that player 1 chooses ( $a, e$ ) cannot be part of a "fully rational" theory from period 1 onwards. Therefore, our concept discards this type of reasoning by player 2.

Example 2. We next move to a more complex dynamic game with "non-trivial" information sets, containing more than one history. Consider the dynamic game from Figure 3. Note that the information sets $h_{2}, h_{3}$ and $h_{5}$ are non-trivial.

In the dynamic game there are six time periods: Period 1 with information set $h_{1}$, period 2 with information set $h_{2}$, period 3 with information sets $h_{3}$ and $h_{4}$, period 4 with information sets $h_{5}$ and $h_{6}$, period 5 with information set $h_{7}$, and period 6 with only terminal histories. To run the forward and backward rationalizability procedure, we thus start at period 5 .

Period 5. At information set $h_{7}$, player 3's strategy $(i, o)$ is never optimal for any conditional belief, whereas the strategy $(i, n)$ is. Thus, only player 3's strategies $g, h$ and $(i, n)$ are optimal for some conditional belief vector from period 5 onwards. As such,

$$
S_{3}^{5.1}=\{g, h,(i, n)\} .
$$

Moreover, we have that $S_{1}^{5.1}=S_{1}$ and $S_{2}^{5.1}=S_{2}$. Hence,

$$
\begin{gathered}
B_{1}^{5.2}=\left\{b_{1} \in B_{1} \mid b_{1} \text { strongly believes } S_{2} \times\{g, h,(i, n)\}\right\} \\
=\left\{b_{1} \in B_{1} \mid b_{1}\left(h_{1}\right)\left(S_{2} \times\{g, h,(i, n)\}\right)=b_{1}\left(h_{3}\right)\left(S_{2} \times\{g, h,(i, n)\}\right)=1\right\},
\end{gathered}
$$

and

$$
\begin{aligned}
& B_{2}^{5.2}=\left\{b_{2} \in B_{2} \mid b_{2} \text { strongly believes } S_{1} \times\{g, h,(i, n)\}\right\} \\
&=\left\{b_{2} \in B_{2} \mid b_{2}\left(h_{2}\right)\left(S_{1} \times\{g, h,(i, n)\}\right)=\right. \\
&\left.b_{2}\left(h_{5}\right)\left(S_{1} \times\{g, h,(i, n)\}\right)=b_{2}\left(h_{6}\right)(\{b\} \times\{(i, n)\})=1\right\}
\end{aligned}
$$

Finally, $B_{3}^{5.2}=B_{3}$. As no further restrictions can be derived after this step, the procedure from Period 5 onwards is hereby complete.
Period 4. At $h_{5}$, both choices $j$ and $k$ of player 2 are optimal for some conditional belief vector in $B_{2}^{5.2}$.
At $h_{6}$, player 2's conditional belief must be part of $B_{2}^{5.2}$ above, and hence player 2 must at $h_{6}$ assign probability 1 to player 3 choosing $n$ at $h_{7}$. But then, player 2's choice $l$ cannot be optimal at $h_{6}$ for any conditional belief vector in $B_{2}^{5.2}$, whereas the choice $m$ can. Hence,

$$
S_{2}^{4.1}=\{(c,(d, j, m),(d, k, m)\} .
$$

Moreover, $S_{1}^{4.1}=S_{1}$ and $S_{3}^{4.1}=S_{3}^{5.1}=\{g, h,(i, n)\}$. We then have that

$$
\begin{gathered}
B_{1}^{4.2}=\left\{b_{1} \in B_{1}^{5.2} \mid b_{1} \text { strongly believes }\{(c,(d, j, m),(d, k, m)\} \times\{g, h,(i, n)\}\}\right. \\
=\left\{b_{1} \in B_{1} \mid b_{1}\left(h_{1}\right)(\{(c,(d, j, m),(d, k, m)\} \times\{g, h,(i, n)\})\right. \\
=b_{1}\left(h_{3}\right)(\{(c,(d, j, m),(d, k, m)\} \times\{g, h,(i, n)\})=1\}
\end{gathered}
$$

and

$$
\begin{aligned}
& B_{3}^{4.2}=\left\{b_{3} \in B_{3}^{5.2} \mid b_{3} \text { strongly believes } S_{1} \times\{(c,(d, j, m),(d, k, m)\}\}\right. \\
&=\left\{b_{3} \in B_{3} \mid b_{3}\left(h_{4}\right)(\{b\} \times\{(d, j, m),(d, k, m)\}=1\},\right.
\end{aligned}
$$

whereas $B_{2}^{4.2}=B_{2}^{5.2}$.
As no further restrictions can be derived after this step, the procedure from Period 4 onwards is hereby complete.
Period 3. At $h_{3}$, both of player 1's strategies $(a, e)$ and $(a, f)$ can be optimal for some conditional belief vector in $B_{1}^{4.2}$. Thus,

$$
S_{1}^{3.1}=S_{1} .
$$

At $h_{4}$, player 3's conditional belief must be part of $B_{3}^{4.2}$, and hence player 3 must believe that player 2 will choose $m$ at $h_{6}$. As such, player 3 expects the utility 10 by choosing $i$ at $h_{4}$, whereas $g$ gives him only 8. This renders the strategy $g$ suboptimal for player 3 at $h_{4}$. Hence,

$$
S_{3}^{3.1}=\{h,(i, n)\} .
$$

As player 2 is not active at any information in Period 3, we have that

$$
S_{2}^{3.1}=S_{2}^{4.1}=\{(c,(d, j, m),(d, k, m)\} .
$$

Thus,

$$
\begin{gathered}
B_{1}^{3.2}=\left\{b_{1} \in B_{1}^{4.2} \mid b_{1} \text { strongly believes }\{(c,(d, j, m),(d, k, m)\} \times\{h,(i, n)\}\}\right. \\
=\left\{b_{1} \in B_{1} \mid b_{1}\left(h_{1}\right)(\{(c,(d, j, m),(d, k, m)\} \times\{h,(i, n)\})\right. \\
=b_{1}\left(h_{3}\right)(\{(c,(d, j, m),(d, k, m)\} \times\{h,(i, n)\})=1\}
\end{gathered}
$$

and

$$
\begin{gathered}
B_{2}^{3.2}=\left\{b_{2} \in B_{2}^{4.2} \mid b_{2} \text { strongly believes } S_{1} \times\{h,(i, n)\}\right. \\
=\left\{b_{2} \in B_{2} \mid b_{2}\left(h_{2}\right)\left(S_{1} \times\{h,(i, n)\}\right)=\right. \\
b_{2}\left(h_{5}\right)((\{(a, e),(a, f)\} \times\{h,(i, n)\}) \cup(\{b\} \times\{h\})) \\
\left.=b_{2}\left(h_{6}\right)(\{b\} \times\{(i, n)\})=1\right\},
\end{gathered}
$$

whereas

$$
\begin{aligned}
& B_{3}^{3.2}=\left\{b_{3} \in B_{3}^{4.2} \mid b_{3} \text { strongly believes } S_{1} \times\{(c,(d, j, m),(d, k, m)\}\}\right. \\
&=\left\{b_{3} \in B_{3} \mid b_{3}\left(h_{4}\right)(\{b\} \times\{(d, j, m),(d, k, m)\}=1\} .\right.
\end{aligned}
$$

Since we can derive no further restrictions after this step, this concludes the procedure from Period 3 onwards.
Period 2. At the information set $h_{2}$, each of player 2's strategies in $S_{2}^{3.1}$ can be optimal for some conditional belief vector in $B_{2}^{3.2}$. Hence, $S_{2}^{2.1}=S_{2}^{3.1}$. As a consequence, the strategy sets and the sets of conditional belief vectors for each of the players remain the same as in Period 3.
Period 1. Round 1. At $h_{1}$, player 1 can guarantee utility 10 by choosing $b$. Since the strategy $(a, e)$ yields him at most 5 , we conclude that the strategy $(a, e)$ is suboptimal for player 1 at $h_{1}$. Therefore,

$$
S_{1}^{1.1}=\{(a, f), b\}
$$

Moreover,

$$
S_{2}^{1.1}=S_{2}^{3.1}=\{(c,(d, j, m),(d, k, m)\}
$$

and

$$
S_{3}^{1.1}=S_{3}^{3.1}=\{h,(i, n)\} .
$$

Round 2. Thus, $B_{1}^{1.2}=B_{1}^{3.2}$, and

$$
\begin{gathered}
B_{2}^{1.2}=\left\{b_{2} \in B_{2}^{3.2} \mid b_{2} \text { strongly believes }\{(a, f), b\} \times\{h,(i, n)\}\right. \\
=\left\{b_{2} \in B_{2} \mid b_{2}\left(h_{2}\right)(\{(a, f), b\} \times\{h,(i, n)\})=\right. \\
b_{2}\left(h_{5}\right)((\{(a, f)\} \times\{h,(i, n)\}) \cup(\{b\} \times\{h\})) \\
\left.=b_{2}\left(h_{6}\right)(\{b\} \times\{(i, n)\})=1\right\},
\end{gathered}
$$

whereas

$$
\begin{gathered}
B_{3}^{1.2}=\left\{b_{3} \in B_{3}^{3.2} \mid b_{3} \text { strongly believes }\{(a, f), b\} \times\{(c,(d, j, m),(d, k, m)\}\}\right. \\
=\left\{b_{3} \in B_{3} \mid b_{3}\left(h_{4}\right)(\{b\} \times\{(d, j, m),(d, k, m)\}=1\} .\right.
\end{gathered}
$$

Note that at $h_{5}$, player 2 can only assign positive probability to the opponents' strategy combinations in $(\{(a, f)\} \times\{h,(i, n)\}) \cup(\{b\} \times\{h\})$. Thus, at $h_{5}$ player 2 can only assign positive probability to the second and fourth history. But then, player 2 should definitely choose $k$ at $h_{5}$, and we thus have that

$$
S_{2}^{1.2}=\{(c,(d, k, m)\}
$$

Moreover, $S_{1}^{1.2}=S_{1}^{1.1}$ and $S_{3}^{1.2}=S_{3}^{1.1}$.
Round 3. As such,

$$
\begin{gathered}
B_{1}^{1.3}=\left\{b_{1} \in B_{1}^{1.2} \mid b_{1} \text { strongly believes }\{(c,(d, k, m)\} \times\{h,(i, n)\}\}\right. \\
=\left\{b_{1} \in B_{1} \mid b_{1}\left(h_{1}\right)\left(\{(c,(d, k, m)\} \times\{h,(i, n)\})=b_{1}\left(h_{3}\right)(\{(c,(d, k, m)\} \times\{h,(i, n)\})=1\}\right.\right.
\end{gathered}
$$

and

$$
\begin{gathered}
B_{3}^{1.3}=\left\{b_{3} \in B_{3}^{1.2} \mid b_{3} \text { strongly believes }\{(a, f), b\} \times\{(c,(d, k, m)\}\}\right. \\
=\left\{b_{3} \in B_{3} \mid b_{3}\left(h_{4}\right)(\{b\} \times\{(d, k, m)\}=1\}\right.
\end{gathered}
$$

whereas $B_{2}^{1.3}=B_{2}^{1.2}$.
Hence, at $h_{1}$ player 1 believes that player 2 chooses either $c$ or $(d, k, m)$. But then, by choosing $(a, f)$ player 1 believes to obtain at least 15 . Since by choosing $(a, e)$ he believes to get at most 5 , and by choosing $b$ he believes to get 10, the strategies $(a, e)$ and $b$ are suboptimal for player 1 at $h_{1}$. Thus,

$$
S_{1}^{1 \cdot 3}=\{(a, f)\} .
$$

At $h_{4}$, player 3 believes that player 2 will choose strategy $(d, k, m)$. But then, the only optimal strategy for player 3 at $h_{4}$ is $h$, and hence

$$
S_{3}^{1.3}=\{h\} .
$$

Moreover, $S_{2}^{1.3}=S_{2}^{1.2}$.
Round 4. We have that

$$
\begin{gathered}
B_{1}^{1.4}=\left\{b_{1} \in B_{1}^{1.3} \mid b_{1} \text { strongly believes }\{(c,(d, k, m)\} \times\{h\}\}\right. \\
=\left\{b_{1} \in B_{1} \mid b_{1}\left(h_{1}\right)\left(\{(c,(d, k, m)\} \times\{h\})=b_{1}\left(h_{3}\right)(\{(c,(d, k, m)\} \times\{h\})=1\}\right.\right. \\
B_{2}^{1.4}=\left\{b_{2} \in B_{2}^{1.3} \mid b_{2} \text { strongly believes }\{(a, f)\} \times\{h\}\right. \\
=\left\{b_{2} \in B_{2} \mid b_{2}\left(h_{2}\right)(\{(a, f)\} \times\{h\})=b_{2}\left(h_{5}\right)(\{(a, f) \times\{h\})=1\},\right.
\end{gathered}
$$

whereas

$$
B_{3}^{1.4}=\left\{b_{3} \in B_{3}^{1.3} \mid b_{3} \text { strongly believes }\{(a, f)\} \times\{(c,(d, k, m)\}\}=B_{3}^{1.3} .\right.
$$

Hence, at $h_{2}$ player 2 must believe that player 1 chooses $(a, f)$. But then, among the strategies in $S_{2}^{1.3}$, the only optimal strategy for player 2 at $h_{2}$ is $(d, k, m)$. Hence,

$$
S_{2}^{1.4}=\{(d, k, m)\}
$$

whereas $S_{1}^{1.4}=S_{1}^{1.3}=\{(a, f)\}$ and $S_{3}^{1.4}=S_{3}^{1.3}=\{h\}$.
Round 5. We finally have that

$$
\begin{gathered}
B_{1}^{1.5}=\left\{b_{1} \in B_{1}^{1.4} \mid b_{1} \text { strongly believes }\{(d, k, m)\} \times\{h\}\right\} \\
=\left\{b_{1} \in B_{1} \mid b_{1}\left(h_{1}\right)(\{(d, k, m)\} \times\{h\})=b_{1}\left(h_{3}\right)(\{(d, k, m)\} \times\{h\})=1\right\}
\end{gathered}
$$

and

$$
\begin{gathered}
B_{2}^{1.5}=\left\{b_{2} \in B_{2}^{1.4} \mid b_{2} \text { strongly believes }\{(a, f)\} \times\{h\}\right. \\
=\left\{b_{2} \in B_{2} \mid b_{2}\left(h_{2}\right)(\{(a, f)\} \times\{h\})=b_{2}\left(h_{5}\right)\left(\{(a, f) \times\{h\})=b_{2}\left(h_{6}\right)(\{b\} \times\{(i, n)\})=1\right\},\right.
\end{gathered}
$$

whereas

$$
\begin{gathered}
B_{3}^{1.5}=\left\{b_{3} \in B_{3}^{1.4} \mid b_{3} \text { strongly believes }\{(a, f)\} \times\{(d, k, m)\}\right\} \\
=\left\{b_{3} \in B_{3} \mid b_{3}\left(h_{4}\right)(\{b\} \times\{(d, k, m)\}=1\} .\right.
\end{gathered}
$$

This is where the procedure terminates. In particular, we see that the unique forward and backward rationalizable strategies for the players are $(a, f),(d, k, m)$ and $h$, respectively.

## 4 Epistemic Characterization

In this section we investigate what the concept of forward and backward rationalizability entails in terms of reasoning. To this purpose, we offer epistemic conditions on the players' belief hierarchies such that the optimal strategies under these belief hierarchies are precisely the forward and backward rationalizable strategies. Before doing so, we first recall the definition of a (universal) type space for dynamic games, and subsequently formalize the notion of strong belief and optimal choice for types in a type space.

### 4.1 Type Space

The epistemic conditions we introduce will impose restrictions on the belief hierarchies that the players may have. Such belief hierarchies may conveniently be encoded by means of types in a type space. To formalize a type space, we need the following definition and pieces of notation. A topological space $(X, \mathcal{O})$ is called Polish if it is separable and completely metrizable. By $\Sigma(X)$ we denote the Borel $\sigma$-algebra on $X$,
that is, the smallest $\sigma$-algebra that contains all open sets, whereas $\Delta(X)$ denotes the set of all probability measures on $(X, \Sigma(X))$. We endow $\Delta(X)$ with the smallest topology $\mathcal{O}_{\Delta(X)}$ such that each of the sets $\left\{\mu \in \Delta(X) \mid \int_{X} f d \mu \in O\right\}$ is open in $\Delta(X)$, where $f$ runs over all bounded continuous functions $f: X \rightarrow \mathbf{R}$ and $O$ runs over all open subsets of the reals. By Kechris (1995), Theorem 17.23, ( $\left.\Delta(X), \mathcal{O}_{\Delta(X)}\right)$ is again a Polish space. We then consider $\Delta(X)$ as a measurable space that is endowed with the Borel $\sigma$-algebra (generated by $\left.\mathcal{O}_{\Delta(X)}\right)$. It is a well-known fact that a continuous map between two topological spaces is measurable if both of these spaces are endowed with their respective Borel $\sigma$-algebras.

Definition 4.1 (Type space) A type space $\mathcal{T}=\left(\left(T_{i}, \mathcal{O}_{i}\right), \beta_{i}\right)_{i \in I}$ specifies, for every player $i$,
(a) a Polish type space $\left(T_{i}, \mathcal{O}_{i}\right)$, and
(b) a continuous belief mapping $\beta_{i}$, which assigns to every type $t_{i} \in T_{i}$ and information set $h \in H_{i}$ a probabilistic belief $\beta_{i}\left(t_{i}, h\right) \in \Delta\left(S_{-i}(h) \times T_{-i}\right)$.

Moreover, the types must satisfy Bayesian updating whenever possible, that is, for every player $i$, every type $t_{i} \in T_{i}$, and every two information sets $h, h^{\prime} \in H_{i}$ where $h^{\prime}$ follows $h$ and $\beta_{i}\left(t_{i}, h\right)\left(S_{-i}\left(h^{\prime}\right) \times T_{-i}\right)>0$, we have that

$$
\beta_{i}\left(t_{i}, h^{\prime}\right)\left(\left\{s_{-i}\right\} \times E_{-i}\right)=\frac{\beta_{i}\left(t_{i}, h\right)\left(\left\{s_{-i}\right\} \times E_{-i}\right)}{\beta_{i}\left(t_{i}, h\right)\left(S_{-i}\left(h^{\prime}\right) \times T_{-i}\right)}
$$

for every $s_{-i} \in S_{-i}\left(h^{\prime}\right)$ and every $E_{-i} \in \Sigma\left(T_{-i}\right)$.
For our epistemic characterization we need to work with a universal type space. To explain what it is, we must first introduce the notion of a type morphism.

Definition 4.2 (Type morphism) Consider two type spaces $\mathcal{T}=\left(\left(T_{i}, O_{i}\right), \beta_{i}\right)_{i \in I}$ and $\mathcal{T}^{\prime}=\left(\left(T_{i}^{\prime}, O_{i}^{\prime}\right), \beta_{i}^{\prime}\right)_{i \in I}$. A type morphism from $\mathcal{T}$ to $\mathcal{T}^{\prime}$ is a tuple $\left(f_{i}\right)_{i \in I}$ of continuous functions $f_{i}: T_{i} \rightarrow T_{i}^{\prime}$ such that, for every player $i$, every type $t_{i} \in T_{i}$, and every information set $h \in H_{i}$ we have that

$$
\beta_{i}^{\prime}\left(f_{i}\left(t_{i}\right), h\right)\left(\times_{j \neq i}\left(\left\{s_{j}\right\} \times E_{j}^{\prime}\right)\right)=\beta_{i}\left(t_{i}, h\right)\left(\times_{j \neq i}\left(\left\{s_{j}\right\} \times f_{j}^{-1}\left(E_{j}^{\prime}\right)\right)\right.
$$

for every opponents' strategy combination $\left(s_{j}\right)_{j \neq i} \in S_{-i}(h)$ and every measurable set $\times_{j \neq i} E_{j}^{\prime} \subseteq \times_{j \neq i} T_{j}^{\prime}$ of opponents' type combinations.

A type space is then called universal if every other type space can be uniquely embedded into it by means of a type morphism.

Definition 4.3 (Universal type space) A type space $\mathcal{T}$ is universal ${ }^{6}$ if for every other type space $\mathcal{T}^{\prime}$ there is a unique type morphism from $\mathcal{T}^{\prime}$ to $\mathcal{T}$.

It turns out that every two universal type spaces are isomorphic. As such, we can speak about the universal type space. Battigalli and Siniscalchi (1999), Guarino (2022) and Fukuda (2023) have shown that we can always construct a universal type space in our setting.

[^6]
### 4.2 Strong Belief

Consider a type space $\mathcal{T}=\left(\left(T_{i}, \mathcal{O}_{i}\right), \beta_{i}\right)_{i \in I}$, a type $t_{i} \in T_{i}$ and an event $E_{-i} \in \Sigma\left(S_{-i} \times T_{-i}\right)$. The type $t_{i}$ is said to strongly believe the event $E_{-i}$ if it assigns probability 1 to the event whenever possible. That is,

$$
\beta_{i}\left(t_{i}, h\right)\left(E_{-i}\right)=1 \text { at all } h \in H_{i} \text { where } E_{-i} \cap\left(S_{-i}(h) \times T_{-i}\right) \neq \emptyset .
$$

### 4.3 Optimal Choice

Consider a type $t_{i} \in T_{i}$, a strategy $s_{i} \in S_{i}$ and an information set $h \in H_{i}\left(s_{i}\right)$ that can possibly be reached by $s_{i}$. Then, we denote by

$$
u_{i}\left(s_{i}, t_{i}, h\right):=\sum_{s_{-i} \in S_{-i}(h)} \beta_{i}\left(t_{i}, h\right)\left(\left\{s_{-i}\right\} \times T_{-i}\right) \cdot u_{i}\left(z\left(s_{i}, s_{-i}\right)\right)
$$

the expected utility induced by $s_{i}$ at $h$ for the type $t_{i}$. The strategy $s_{i}$ is optimal for the type $t_{i}$ at information set $h$ if $u_{i}\left(s_{i}, t_{i}, h\right) \geq u_{i}\left(s_{i}^{\prime}, t_{i}, h\right)$ for all other strategies $s_{i}^{\prime} \in S_{i}(h)$. For a given period $m$, we say that strategy $s_{i}$ is optimal for the type $t_{i}$ from period $m$ onwards if for every period $\tau \geq m$, and every information set $h \in H_{i}\left(s_{i}\right) \cap H^{\tau}$, the strategy $s_{i}$ is optimal for type $t_{i}$ at $h .{ }^{7}$ For a given set of types $\hat{T}_{i} \in \Sigma\left(T_{i}\right)$, we denote by

$$
\left(S_{i} \times \hat{T}_{i}\right)^{r a t, m}:=\left\{\left(s_{i}, t_{i}\right) \in S_{i} \times \hat{T}_{i} \mid s_{i} \text { optimal for } t_{i} \text { from period } m \text { onwards }\right\}
$$

the event that player $i$ chooses rationally from period $m$ onwards and that $i$ 's type belongs to $\hat{T}_{i}$.
The following result states that the event of choosing rationally from a certain period onwards is always a "well-behaved" set.

Lemma 4.1 (Rationality is a measurable event) Suppose that $\hat{T}_{i}$ is a closed (measurable) subset of $T_{i}$. Then, the set $\left(S_{i} \times \hat{T}_{i}\right)^{r a t, m}$ is a closed (measurable) subset of $S_{i} \times T_{i}$.

This result will be important for guaranteeing that the epistemic conditions below are all well-defined. It will also play a key role in the proof of our epistemic characterization.

### 4.4 Epistemic Characterization

The epistemic conditions we impose on the players' types are as follows: First, we focus on the last period $M$ where players have to move. A player must (M.1) strongly believe in the event that every opponent chooses rationally from period $M$ onwards, (M.2) strongly believe in the event that every opponent chooses rationally from period $M$ onwards and that every opponent satisfies ( $M .1$ ), and so on. These conditions together yield common backward strong belief in rationality from period $M$ onwards. We refer to this event as $(M)$. In fact, since every player moves at most once at period $M$, event ( $M$ ) is equivalent to common belief in rationality at period $M$.

[^7]We then move to period $M-1$. A player must ( $M-1.1$ ) strongly believe in the event that every opponent chooses rationally from period $M-1$ onwards and that every opponent satisfies $(M)$. Moreover, a player must ( $M-1.2$ ) strongly believe in the event that every opponent chooses rationally from period $M-1$ onwards and that every opponent satisfies $(M-1.1)$, and so on. These conditions together yield common backward strong belief in rationality from period $M-1$ onwards.

We then continue in this fashion until we reach the beginning of the game. The final restrictions on the types are called common backward strong belief in rationality.

Definition 4.4 (Common backward strong belief in rationality) For every period $m$, number $k \in$ $\{0,1, \ldots\}$ and player $i$, we define the sets of types $T_{i}^{m . k}$ that express $k$-fold backward strong belief in rationality from period $m$ onwards. These sets $T_{i}^{m . k}$ are inductively defined as follows.
Period M. Set $T_{i}^{M .0}:=T_{i}$ for every player $i$. For every $k \geq 1$, inductively define

$$
T_{i}^{M . k}:=\left\{t_{i} \in T_{i}^{M . k-1} \mid t_{i} \text { strongly believes } \times_{j \neq i}\left(S_{j} \times T_{j}^{M . k-1}\right)^{r a t, M}\right\} .
$$

Set $T_{i}^{M}:=\cap_{k \geq 0} T_{i}^{M . k}$ for every player $i$.
Period $m \leq M-1$. Set $T_{i}^{m .0}:=T_{i}^{m+1}$ for every player $i$. For every $k \geq 1$, inductively define

$$
T_{i}^{m . k}:=\left\{t_{i} \in T_{i}^{m . k-1} \mid t_{i} \text { strongly believes } \times_{j \neq i}\left(S_{j} \times T_{j}^{m . k-1}\right)^{\text {rat }, m}\right\} .
$$

Set $T_{i}^{m}:=\cap_{k \geq 0} T_{i}^{m . k}$ for every player $i$.
For a given period $m$ and round $k$, a type $t_{i}$ is said to express up to $k$-fold backward strong belief in rationality from period $m$ onwards if $t_{i} \in T_{i}^{m . k}$. The type is said to express common backward strong belief in rationality from period $m$ onwards if $t_{i} \in T_{i}^{m}$. The type $t_{i}$ is said to express common backward strong belief in rationality if $t_{i} \in T_{i}^{L}$, where $L$ is the first period in the game.

The following result guarantees that the epistemic conditions imposed above lead to "well-behaved" sets.
Lemma 4.2 (Epistemic conditions lead to closed sets) Each of the sets $T_{i}^{m . k}$ and $T_{i}^{m}$ above is a closed subset of $T_{i}$.

Let us now have a closer look at the epistemic conditions above. The conditions imply that at every information set where a player has to move, he looks for the earliest period $m$ and the highest degree $k$ such that it is possible to believe that (i) every player chooses rationally from period $m$ onwards and expresses common backward strong belief in rationality from period $m$ onwards, and (ii) every player chooses rationally from period $m-1$ onwards and expresses up to $k$-fold backward strong belief in rationality from period $m-1$ onwards. Moreover, he will then believe (i) and (ii). This may be viewed as a best rationalization principle for the epistemic concept above.

From this best rationalization principle it is clear that epistemic priority is given to backward induction reasoning: If a player is at an information set, he first looks for the earliest period $m$ such that it is possible
to believe that every player chooses rationally from period $m$ onwards and expresses common backward strong belief in rationality from period $m$ onwards. In that case, the player will express common backward strong belief in rationality from period $m$ onwards, and hence will believe, in particular, that every opponent will choose rationally from period $m$ onwards. Only afterwards will he think about period $m-1$, and look for the highest degree $k$ such that it is possible to believe that, in addition, every player chooses rationally from period $m-1$ onwards and expresses up to $k$-fold backward strong belief in rationality from period $m-1$ onwards.

The following result shows that the epistemic conditions in common backward strong belief in rationality single out precisely those strategies that are forward and backward rationalizable.

Theorem 4.1 (Epistemic characterization) Consider the universal type space $\mathcal{T}=\left(\left(T_{i}, \mathcal{O}_{i}\right), \beta_{i}\right)_{i \in I}$. Then, for every player $i$ and strategy $s_{i} \in S_{i}$, the following holds:
(a) strategy $s_{i}$ is forward and backward rationalizable, if and only if, $s_{i}$ is optimal from the first period onwards for a type $t_{i} \in T_{i}$ that expresses common backward strong belief in rationality,
(b) if $m \leq M-1$ then $s_{i} \in S_{i}^{m .0}$, if and only if, $s_{i}$ is optimal from period $m+1$ onwards for a type $t_{i} \in T_{i}^{m+1}$ that expresses common backward strong belief in rationality from period $m+1$ onwards, and
(c) if $k \geq 0$ then $s_{i} \in S_{i}^{m . k+1}$, if and only if, $s_{i}$ is optimal from period $m$ onwards for a type $t_{i} \in T_{i}^{m . k}$ that expresses up to $k$-fold backward strong belief in rationality from period $m$ onwards.

In particular, since we know from Theorem 3.1 that forward and backward rationalizable strategies always exist, it follows that there is always a type that expresses common backward strong belief in rationality. That is, the system of epistemic conditions we offer never leads to logical contradictions.

A major difference with extensive-form rationalizability is that forward and backward rationalizability requires players to do forward induction reasoning from a certain period onwards, in a backward inductive fashion. Extensive-form rationalizability, in contrast, always requires players to do the forward induction reasoning in the whole game, that is, from the first period onwards.

As such, we can also consider a bounded rationality version of forward and backward rationalizability in which players only do the forward induction reasoning from period $M$ onwards, from period $M-1$ onwards, until we reach period $m$. Players would thus not actively reason about choices that are made before period $m$. Parts (b) and (c) in Theorem 4.1 reveal what has to be imposed, in terms of reasoning, to establish such a bounded rationality variant.

## 5 Relation with Backwards Rationalizability

In this section we start by showing that our concept of forward and backward rationalizability is a refinement of backwards rationalizability in terms of strategies. In epistemic terms, this means that our concept will always reason within the bounds of common belief in future rationality (Perea (2014)). It is shown that the reasoning of extensive-form rationalizability may be in conflict with common belief in future rationality,
and we explain why in some situations this may lead to unreasonable behavior after observing surprising past moves. We conclude by looking at two alternative procedures that also combine backward and forward induction reasoning, and show by means of examples that these may be different from our procedure in terms of strategies.

### 5.1 Refinement of Backwards Rationalizability

In the game of Figure 2 we saw that forward and backward rationalizability selects a different strategy for player 2 than extensive-form rationalizability. The reason was that according to the former concept, player 2 , at a given information set $h$, only interprets player 1's past move as a rational move if this is compatible with the completed reasoning from $h$ onwards. This shows that forward and backward rationalizability is, above all, a forward looking concept, and thus gives priority to backward induction reasoning.

This intuition will be confirmed in this section, where we show that forward and backward rationalizability always yields a refinement - both in terms of strategies and beliefs - of the backwards rationalizability procedure, as defined in Penta (2015) and Perea (2014).

We are now ready to state the announced result.
Theorem 5.1 (Relation with backwards rationalizability ) Every strategy and conditional belief vector that is forward and backward rationalizable, is also backwards rationalizable.

That is, our concept of forward and backward rationalizability will always reason in line with backwards rationalizability, even if a player is surprised by some opponents' past moves. However, as the game in Figure 2 shows, our concept may be more restrictive since it additionally imposes some forward induction reasoning. Indeed, in that game backwards rationalizability allows player 2 to choose either $d$ or $(c, h)$, as it does not perform any forward induction reasoning. Our concept, in turn, uniquely selects player 2's strategy $(c, h)$.

### 5.2 Belief in Future Rationality

In Perea (2014) it is shown that backwards rationalizability can be epistemically characterized by the conditions of common belief in future rationality, stating that a player always believes that his opponents will choose rationally now and in the future, that a player always believes that his opponents always believe that the other players will chooses rationally now and in the future, and so on. Hence, even if a player is suprised by an opponent's past move, which may possibly lead him to conclude that his opponent has chosen irrationally in the past, he will still believe that the same opponent will "recover" and choose rationally from now on.

As, by Theorem 5.1, forward and backward rationalizability refines the reasoning of backwards rationalizability, it follows that the former concept always reasons within the bounds set by common belief in future rationality. In particular, a player will only interpret an opponent's past move as a signal for the opponent's future behavior - a typical forward inductive inference - if this is in accordance with common

Figure 4: Double outside option game with a bet for the third player
belief in future rationality. If, for instance, the opponent's observed past move could only be rational if the opponent believes that some other players will choose irrationally in the future, then, according to our concept, the player should not view this move as a credible signal for future behavior.

In this sense, our concept is fundamentally different from extensive-form rationalizability. To further illustrate this, consider the game in Figure 4. This is a three-player double outside game, where the third player has to "bet" on the behavior of the first two players after they have both foregone the outside option. In that case, player 1 must choose between $e$ and $f$, player 2 must choose between $g$ and $h$, whereas player 3 must choose between $l$ and $r$ (left matrix or right matrix). These choices by players 1,2 and 3 are assumed to occur simultaneously. Note that $r$ will only be optimal for player 3 if he believes, with sufficiently high probability, that players 1 and 2 miscoordinate on $e$ and $h$ at information set $h_{3}$.

According to extensive-form rationalizability, player 3 will conclude at $h_{3}$ that players 1 and 2 will go for $e$ and $h$, respectively, and therefore player 3 will choose $r$. To see this, note that $a$ for player 1 can only be optimal at $h_{1}$ if he chooses $e$ at $h_{3}$, and that $c$ for player 2 can only be optimal at $h_{2}$ if he chooses $h$ at $h_{3}$.

But assume now that player 1 would choose optimally at $h_{3}$ given his beliefs there. According to extensive-form rationalizability, player 1 will believe at $h_{3}$ that player 2 chooses $h$, for the same reasons as outlined above. If player 1 chooses optimally at $h_{3}$, then he would go for $f$ and not $e$, rendering $r$ suboptimal for player 3. In that sense, the choice $r$ selected by extensive-form rationalizability is a risky choice for player 3 , as this bet is based on the assumption that player 1 will not choose optimally given his belief at $h_{3}$. That is, player 3 would not believe in player 1's present rationality at $h_{3}$, and his reasoning would thus contradict common belief in future rationality.

The concept of forward and backward rationalizability prescribes a completely different line of reasoning
for player 3 here. If player 3 finds himself at $h_{3}$, then he first asks whether there is a plausible theory from information set $h_{2}$ onwards that could explain the event of reaching $h_{3}$. Such a theory can indeed be found: For player 2 it is only optimal to choose $c$ at $h_{2}$ if he would choose $h$ at $h_{3}$. Therefore, player 3 will believe at $h_{3}$ that player 2 will choose $h$, and will believe that player 1 also believes at $h_{3}$ that player 2 chooses $h$. Assuming that player 1 chooses optimally at $h_{3}$, player 3 then believes that player 1 chooses $f$ at $h$. Hence, by analyzing the game from $h_{2}$ onwards, player 3 comes up with a unique prediction for the behavior of players 1 and 2 at $h_{3}$, which is that they choose $f$ and $h$, respectively.

Clearly, this prediction cannot be refined any further by subsequently analyzing the game from $h_{1}$ onwards, and therefore forward and backward rationalizability leads player 3 to believe that players 1 and 2 will choose $f$ and $h$ at $h_{3}$, and player 3 will thus choose $l$. Note that player 1's choice $f$ is optimal at $h_{3}$ if he believes that player 2 chooses $h$ there, and vice versa. As such, player 3's reasoning about the behavior of players 1 and 2 is in line with common belief in future rationality, contrary to player 3's reasoning prescribed by extensive-form rationalizability.

### 5.3 Epistemic Priority

One could argue that in the concept we propose, we give epistemic priority to backward induction reasoning over forward induction reasoning. This may be seen, for instance, from Theorem 5.1 which shows that our concept, in terms of strategies and beliefs, is a refinement of the backward induction concept of backwards rationalizability, but not of extensive-form rationalizability.

It may also be seen epistemically, by looking at Theorem 4.1: We first impose common strong belief in rationality from the last period onwards, and keep these restrictions when we move to restrictions on reasoning from the penultimate period onwards. In turn, the restrictions on the reasoning from the penultimate period onwards are maintained when restricting the reasoning from earlier periods onwards, and so on. As such, a player will always believe, at every period, that his opponents will choose rationally in the periods that lie ahead - a typical backward induction restriction.

But we could also change the epistemic priority, by first applying the extensive-form rationalizability procedure, and subsequently refining it by the backwards rationalizability procedure. In that alternative procedure we would thus give epistemic priority to forward induction reasoning over backward induction reasoning.

This concept would be different from ours, at least in terms of strategies and beliefs. Consider, for instance, the game from Figure 1, where our concept would yield the strategy $c$ for player 2, whereas the alternative procedure would uniquely select strategy $(d, g)$ for player 2 . To see this, note that backwards rationalizability always leads to the unique backward induction strategies in perfect information games without relevant ties, like the one in Figure 1. As player 2's backward induction strategy is $c$, and our concept is a refinement of backwards rationalizability in terms of strategies, our concept will uniquely select $c$ as well. On the other hand, we have seen in the introduction that player 2's unique extensive-form rationalizable strategy is $(d, g)$. As the alternative procedure is a refinement of extensive-form rationalizability in terms of strategies, it will uniquely select $(d, g)$ also.

For a concept that combines forward and backward induction reasoning, one could also proceed alter-

Figure 5: Triple outside option game
natively, by first applying the backwards rationalizability procedure to the whole game, until we can go no further, after which it is refined by the steps in the extensive-form rationalizability procedure. This would correspond to an instance of $\Delta$-rationalizability (Battigalli (2003), Battigalli and Siniscalchi (2003)) where $\Delta$ consists of the restrictions on beliefs imposed by backwards rationalizability. Like with our procedure, this would also correspond to a scenario where epistemic priority is given to backward induction reasoning, but in a more extreme fashion than we do. Indeed, in the alternative procedure we would first exhaust all the backward induction reasoning in the whole game, after which we exclusively turn to forward induction reasoning in the whole game.

For reasons that will become clear in the following section, the alternative procedure will be equivalent to ours in terms of outcomes. Moreover, like our procedure, it will also refine backwards rationalizability in terms of strategies. However, as the example in Figure 5 will show, both concepts can be different in terms of strategies.

Consider the game from Figure 5. In the alternative procedure, we would start by applying the backwards rationalizability procedure to the whole game. We proceed in a backward inductive fashion here, by first considering the last information set $h_{4}$, where nothing can be eliminated. At $h_{3}$, we eliminate ( $\operatorname{In}, f$ ) for player 2 , after which we can eliminate ( $I n, c$ ) for player 1 at $h_{2}$. Finally, we eliminate ( $\operatorname{In}, r$ ) for player 3 at $h_{1}$. The backwards rationalizable strategies are thus Out, (In,a) and (In,b) for player 1, Out, (In, d) and ( $I n, e$ ) for player 2, and Out and ( $I n, l$ ) for player 3.

If we take this as an input for the extensive-form rationalizability procedure, then in round 1 of the extensive-form rationalizability procedure we can eliminate ( $\operatorname{In}, b$ ) for player 1 and ( $\operatorname{In}, d$ ) for player 2 . Indeed, at $h_{2}$ player 1 must believe that player 2 chooses $O u t$, (In, $d$ ) or ( $\operatorname{In}, e$ ) and that player 3 chooses $(I n, l)$. Hence, player 1 expects at most 1 by choosing ( $I n, b)$ there. Also, player 2 must believe at $h_{3}$ that
player 1 will choose ( $\operatorname{In}, a$ ) or ( $I n, b$ ) and that player 3 will choose ( $I n, l$ ). As such, player 2 expects at most 1 by choosing ( $I n, d$ ) there.

In round 2 we can then eliminate, for similar reasons, ( $\operatorname{In}, a$ ) for player 1 and ( $\operatorname{In}, e$ ) for player 2. In round 3 we can finally eliminate ( $\operatorname{In}, l$ ) for player 3 . Indeed, player 3 must believe at $h_{1}$ that player 1 chooses Out, which yields Out as the only optimal strategy for player 3 at $h_{1}$.

The alternative procedure, where we first apply the backwards rationalizability procedure and then extensive-form rationalizability, thus yields the strategy Out for player 1, Out for player 2, and Out for player 3.

Let us now apply our procedure to this game. Applying the extensive-form rationalizability procedure to the subgame starting at $h_{4}$ yields no eliminations. If we start at $h_{3}$, then we can only eliminate the strategy $(\operatorname{In}, f)$ for player 2. If we start at $h_{2}$, then in round 1 we eliminate the strategy ( $\operatorname{In}, c$ ) for player 1 , as he expects to get at most 2 by choosing $(I n, c)$ at $h_{2}$. In round 2 we would then eliminate the strategy ( $I n, d$ ) for player 2 and the strategy ( $I n, r$ ) for player 3. Indeed, player 2 expects to get at most 1 by playing (In,d), whereas for player 3 choosing $l$ has become better than choosing $r$ at $h_{4}$. In round 3 , we would then eliminate ( $I n, a$ ) and ( $I n, b$ ) for player 1 , since he expects to obtain no more than 1 by choosing either of these two strategies. Finally, we would move to the game starting at $h_{1}$, where we can eliminate the strategy (In,l) for player 3. Our concept would thus yield the strategy Out for player 1, the strategies Out and (In,e) for player 2, and the strategy Out for player 3. As the strategy (In,e) for player 2 was not selected by the alternative procedure, both concepts differ in terms of strategies.

The reason for why our concept allows for player 2's strategy ( $\operatorname{In}, e$ ) but the alternative procedure does not, is the following: The alternative procedure starts by eliminating the strategies ( $\operatorname{In}, f$ ) for player 2, ( $\operatorname{In}, c$ ) for player 1 and ( $I n, r$ ) for player 3. It would then proceed by applying extensive-form rationalizability to the whole game, so that player 2 will conclude at $h_{3}$ that player 1 must be choosing ( $\left.\operatorname{In}, a\right)$. As a consequence player 2 must choose Out at $h_{3}$ according to the alternative procedure.

Our concept proceeds differently: It also starts by eliminating ( $\operatorname{In}, f$ ) for player 2 and ( $\operatorname{In}, c$ ) for player 1. But then, by reasoning from $h_{2}$ onwards, we would eliminate ( $I n, d$ ) for player 2 and ( $\operatorname{In}, r$ ) for player 3. If player 1 believes at $h_{2}$ that player 2 will no longer choose ( $\operatorname{In}, d$ ) and ( $\operatorname{In}, f$ ), both ( $\left.\operatorname{In}, a\right)$ and (In, b) become suboptimal for player 1 at $h_{1}$. As ( $\operatorname{In}, c$ ) was already eliminated for player 1 at an earlier stage, player 2 is no longer forced to discriminate between (In,a) and (In,b), and hence player 2 may still believe at $h_{3}$ that player 1 chooses ( $\operatorname{In}, b$ ). Hence, player 2 may still rationally choose ( $I n, e$ ) at $h_{3}$ according to our concept.

In this example, we thus see that the alternative concept is more restrictive, in terms of strategies, than ours. The reverse may also be true, as the example from Figure 2 shows. We have already seen in the introduction and Section 3.4 that our concept uniquely selects the strategies $b$ for player 1 and $(c, h)$ for player 2.

Suppose now that we would run the alternative procedure. By applying backwards rationalizability first, we would start by eliminating strategy $(c, g)$ for player 2 at $h_{2}$, after which we would eliminate $(a, e)$ and $(a, f)$ for player 1 at $h_{1}$. Indeed, if player 1 believes at $h_{1}$ that player 2 will not choose $(c, g)$, then choosing $a$ can give him at most 1 . Hence, the backwards rationalizable strategies are $b$ for player 1 , and $(c, h)$ and $d$ for player 2. If we use this as the input for the extensive-form rationalizability procedure, then at $h_{2}$ player

2 can no longer discriminate between ( $a, e$ ) and ( $a, f$ ) for player 1 , and hence player 2 may believe at $h_{2}$ that player 1 chooses $(a, e)$ or $(a, f)$. As such, both $d$ and $(c, h)$ can be optimal for player 2 at $h_{2}$, which means that the alternative concept would select both $d$ and $(c, h)$ for player 2 .

The reason for this difference is similar to above, but now with the roles of the two concepts reversed: Under our concept, player 2 will certainly believe at $h_{2}$ that player 1 chooses $(a, f)$ and not $(a, e)$, and therefore only $(c, h)$ is optimal for player 2 . Under the alternative concept, player 2 is no longer forced to discriminate between $(a, e)$ and $(a, f)$, which leaves both $d$ and $(c, h)$ as valid options for player 2.

The last alternative procedure described above thus gives epistemic priority to backward induction reasoning over forward induction reasoning. Similar approaches have been adopted in the equilibrium refinements literature from the eighties and early nineties, where the backward induction concept of sequential equilibrium has been refined by imposing forward induction restrictions. See, for instance, justifiable sequential equilibrium (McLennan (1985)), forward induction equilibrium (Cho (1987)) and stable sets of beliefs (Hillas (1994)).

The issue of epistemic priority is explored in depth by Catonini (2019), who proposes the concept of selective rationalizability. It proceeds by first applying extensive-form rationalizability, after which it is refined by imposing (common strong belief in) some exogenously given restrictions on beliefs. ${ }^{8}$ However, it could happen that these exogenous restrictions are incompatible with the restrictions imposed by extensiveform rationalizability. This will typically be the case when the exogenous restrictions are taken to be the restrictions imposed by backwards rationalizability, because in many dynamic games these restrictions go against the restrictions of extensive-form rationalizability.

The first alternative procedure described above, where we started with the extensive-form rationalizability procedure, and subsequently refined it with the backwards rationalizability procedure, is, strictly speaking, not a selective rationalizability procedure in the sense of Catonini (2019): The restrictions of backwards rationalizability are not being imposed as exogeneous restrictions after completing the extensiveform rationalizability procedure, but rather as "optional" restrictions meant to refine, whenever possible, the reasoning of extensive-form rationalizability.

## 6 Relation with Extensive Form Rationalizability

In this section we show that the forward and backward rationalizability procedure is equivalent, in terms of outcomes, to the extensive-form rationalizability procedure. To prove this result we use the strong belief reduction operator from Perea (2018), transforming every profile of strategy sets into a profile of smaller strategy sets. Perea (2018) showed, for the class of dynamic games with observed past choices, that (a) extensive-form rationalizability can be characterized by the iterated application of the strong belief reduction operator, and (b) the strong belief reduction operator is order independent with respect to outcomes, that is, the final set of induced outcomes will not change if during the iterated application of the strong belief

[^8]operator we opt for a "slower" elimination order in which we do not always eliminate all strategies we can.
In this section we argue that the results (a) and (b) carry over to the more general class of dynamic games we consider in this paper, which allows for unobserved past choices. Moreover, we show that (c) the forward and backward rationalizability procedure corresponds to a specific "slower" elimination order of the iterated application of the strong belief reduction operator. By combining the properties (a), (b) and (c) it then follows that the extensive-form rationalizability procedure and the forward and backward rationalizability procedure always induce the same set of outcomes.

### 6.1 Strong Belief Reduction Operator

A product of strategy sets is a set $D=\times_{i \in I} D_{i}$ where $D_{i} \subseteq S_{i}$ for every player $i$. A reduction operator $r$ assigns to every product of strategy sets $D$ a subset $r(D) \subseteq D$, where $r(D)$ is again a product of strategy sets. In the sequel, we always assume that we are talking about products of strategy sets. A set $E$ with $r(D) \subseteq E \subseteq D$ is a partial reduction of $D$. For a given $k \in \mathbf{N}$, let $r^{k}(D)$ be the $k$-fold application of the operator $r$ to $D$.

For a given product of strategy sets $D$, let $H(D)$ be the collection of information sets that are reached by some strategy profile in $D$.

Definition 6.1 (Strong belief reduction operator) The strong belief reduction operator sb assigns to every product of strategy sets $D=\times_{i \in I} D_{i}$ the set $s b(D)=\times_{i \in I} s b_{i}(D)$, where

$$
\begin{aligned}
& s b_{i}(D):=\left\{s_{i} \in D_{i} \mid \text { there is some } b_{i} \in B_{i} \text { that strongly believes } D_{-i}\right. \\
& \text { such that } \left.s_{i} \text { is optimal for } b_{i} \text { at every } h \in H(D) \cap H_{i}\left(s_{i}\right)\right\} .
\end{aligned}
$$

Recall that $H_{i}\left(s_{i}\right)$ is the collection of information sets for player $i$ that can be reached by $s_{i}$. In Perea (2018), Theorem 2.1, it is shown that for dynamic games with observed past choices, the extensive-form rationalizable strategies are obtained by iteratedly applying the strong belief reduction operator to the full set of strategies. As the proof does not rely on the property of observed past choices, this result holds for all games in our setting as well.

Theorem 6.1 (Characterization of extensive form rationalizability) For every $k \in \mathbf{N}$ and every player $i$, let $S_{i}^{\text {efr,k }}$ be the set of strategies for player $i$ that survive round $k$ of the extensive-form rationalizability procedure. Let $S^{e f r, k}=\times_{i \in I} S_{i}^{e f r, k}$ and $S=\times_{i \in I} S_{i}$. Then, $S^{e f r, k}=s b^{k}(S)$ for every $k \in \mathbf{N}$.

### 6.2 Order Independence with Respect to Outcomes

Consider a reduction operator $r$. An elimination order for $r$ is a finite sequence ( $D^{0}, D^{1}, \ldots, D^{K}$ ) of products of strategy sets such that (a) $D^{0}=S$, (b) $r\left(D^{k}\right) \subseteq D^{k+1} \subseteq D^{k}$ for every $k \in\{0, \ldots, K-1\}$, and (c) $r\left(D^{K}\right)=D^{K}$.

For a product of strategy sets $D$, let $Z(D)$ be the collection of terminal histories reached by strategy profiles in $D$.

Definition 6.2 (Order independence with respect to outcomes) A reduction operator $r$ is order independent with respect to outcomes if for every two elimination orders $\left(D^{0}, D^{1}, \ldots, D^{K}\right)$ and $\left(E^{0}, E^{1}, \ldots, E^{L}\right)$ we have that $Z\left(D^{K}\right)=Z\left(E^{L}\right)$.

Corollary 3.1 in Perea (2018) states that for all dynamic games with observed past choices, the strong belief reduction operator is order independent with respect to outcomes. As it turns out, the proof in Perea (2018) does not rely on the property of observed past choices, and holds for our class of dynamic games as well.

Theorem 6.2 (Order independence with respect to outcomes) The strong belief reduction operator $s b$ is order independent with respect to outcomes.

### 6.3 Outcome Equivalence with Extensive Form Rationalizability

The following result states that the reduction steps in the forward and backward rationalizability procedure correspond to a specific elimination order of the strong belief reduction operator.

Lemma 6.1 (Procedure as elimination order) Let $\left(D^{0}, D^{1}, \ldots, D^{K}\right)$ be the products of strategy sets generated by the forward and backward rationalizability procedure in every round. Then, $\left(D^{0}, D^{1}, \ldots, D^{K}\right)$ is an elimination order of the strong belief reduction operator.

By combining Theorem 6.1, Lemma 6.1 and Theorem 6.2, we conclude that extensive-form rationalizability leads to the same set of outcomes as forward and backward rationalizability.

Theorem 6.3 (Outcome equivalence with extensive form rationalizability) Let $S^{e f r}$ and $S^{f b r}$ be the products of strategy sets induced by the extensive-form rationalizability procedure, and the forward and backward rationalizability procedure, respectively. Then, $Z\left(S^{e f r}\right)=Z\left(S^{f b r}\right)$.

That is, if one would be only interested in the induced outcomes, it makes no difference whether extensiveform rationalizability is used, or forward and backward rationalizability. However, as we have argued before, we believe that the latter concept provides a more compelling theory for how players react to surprises at information sets to which the players initially assign probability zero.

Finally, consider one of the alternative procedures we discussed in Section 5.3, where we first apply the backwards rationalizability procedure, followed by the extensive-form rationalizability procedure. By a proof similar to that of Lemma 6.1, it can be shown that this procedure also corresponds to a specific elimination order of the strong belief reduction operator. But then, it follows in the same way as above that also this procedure is equivalent to extensive-form rationalizability in terms of outcomes. However, recall from Section 5.3 that the two procedures may be different in terms of strategies.

For the other alternative procedure in Section 5.3, where we first apply the extensive-form rationalizability procedure, followed by the backwards rationalizability procedure, things are more complicated, as it does not correspond to a specific elimination order of the strong belief reduction operator. The reason is that
after applying the extensive-form rationalizability procedure, which corresponds to recursively applying the strong belief reduction operator at "full speed", the strong belief reduction operator is not able to induce any further eliminations. At this moment it is not clear to us whether both concepts can be different in terms of outcomes. But we have seen in Section 5.3 that both concepts can be different in terms of strategies.

## 7 Generalization of Battigalli's Theorem

Battigalli (1997) has shown that in every dynamic game with perfect information but without relevant ties, extensive-form rationalizability leads to the unique backward induction outcome. Alternative proofs can be found in Catonini (2020), Chen and Micali (2013), Heifetz and Perea (2015) and Perea (2018).

Catonini (2020) and Perea (2017) provide generalizations of this result, by showing that in every dynamic game with observable past choices (but allowing for simultaneous moves), extensive-form rationalizability refines, in terms of outcomes, the concepts of backwards rationalizability and backward dominance, respectively.

However, one of the most attractive properties of extensive-form rationalizability is that in games with imperfect information (that is, where some past choices are unobservable), it allows an active player at an information set to exclude some of the nodes of this information set from consideration. This is so, since reaching those nodes would imply a lower degree of rationality for some players that moved in the past than the remaining "more rational" nodes. Therefore it is of importance to understand the relationship between forward and backward induction especially for games with imperfect information. As is well-known, there are games that allow for more backwards rationalizable outcomes than extensive-form outcomes. ${ }^{9}$ To the best of our knowledge, it was - up to now - unknown whether for games with imperfect information extensive-form rationalizable outcomes are always backwards rationalizable outcomes.

It turns out that in every dynamic game considered in our setup, that is, also in games with imperfect information, every extensive-form rationalizable outcome is indeed backwards rationalizable. This follows immediately from our Theorems 5.1 and 6.3: Take an outcome induced by extensive-form rationalizability. Then, by Theorem 6.3, this outcome will also be induced by forward and backward rationalizability. As, by Theorem 5.1, forward and backward rationalizability refines backwards rationalizability in terms of strategies, it follows that this outcome is also induced by backwards rationalizability. We thus obtain the following result.

Corollary 7.1 (Generalization of Battigalli's theorem) Let $S^{e f r}$ and $S^{b r}$ denote the products of strategy sets induced by the extensive-form rationalizability procedure and the backwards rationalizability procedure, respectively. Then, $Z\left(S^{e f r}\right) \subseteq Z\left(S^{b r}\right)$.

This result, in turn, implies Battigalli's theorem, as in every dynamic game with perfect information but without relevant ties, the concept of backwards rationalizability leads to the unique backward induction

[^9]strategies, and thus, in particular, to the unique backward induction outcome. The existence of extensiveform rationalizable outcomes now implies that this must also be the unique extensive-form rationalizable outcome.

Corollary 7.1 could also be established by using tools from Chen and Micali (2013) ${ }^{10}$ : It can be shown that backwards rationalizability corresponds to a possible, non-finished elimination order of the iterated conditional dominance procedure by Shimoji and Watson (1998). Since Shimoji and Watson (1998) prove that the latter procedure is equivalent to extensive-form rationalizability, and Chen and Micali (2013) show that this procedure is order independent with respect to outcomes, the statement from the corollary follows.

## 8 Supergame Monotonicity

In this section we introduce the principle of supergame monotonicity. Intuitively, it states that, whenever a player is informed that the game was actually preceded by some earlier moves he was initially unaware of, then this new piece of information should only lead him to possibly refine his reasoning, but never to completely overthrow the reasoning he applied before. We start by illustrating the idea by means of an example, after which we formally state the principle. It is then shown that our concept of forward and backward rationalizability satisfies this principle, whereas extensive-form rationalizability violates it. We conclude by observing that backwards rationalizability satisfies supergame monotonicity trivially, that is, the new piece of information will never alter the player's reasoning.

From these findings it follows that, upon learning that the game $\Gamma$ was preceded by some earlier moves, and thus that the actual game is $\hat{\Gamma}$ and not $\Gamma$, forward and backward rationalizability will (i) refine the outcomes induced by extensive-form rationalizability in the smaller game $\Gamma$, and (ii) refine the strategies induced by backwards rationalizability in the smaller game $\Gamma$. In that sense, the forward and backward rationalizability concept will always be in line with forward and backward induction reasoning, even if new information about past moves comes in.

### 8.1 Example

Consider a game $\Gamma$, and suppose that the players in $\Gamma$ receive some additional information about the history that led to the game $\Gamma$. Formally, $\Gamma$ will be embedded into a larger game $\hat{\Gamma}$, which includes $\Gamma$ as a subgame. We call $\hat{\Gamma}$ a supergame of $\Gamma$.

As an illustration, consider Figure 1 and the game $\Gamma$ that starts at information set $h_{2}$. Now suppose that player 2 receives additional information about the history that led to this game. More specifically, player 2 learns that player 1 could have chosen an outside option, $a$, which would have given him a utility of 5 , but player 1 declined this option. Formally, player 2 learns that the game is expanded to the supergame $\hat{\Gamma}$ which starts at information set $h_{1}$.

Supergame monotonicity then states that this additional information may possibly refine the reasoning of the players, but will never overrule it. More precisely, every strategy that can rationally be chosen in

[^10]the smaller game $\Gamma$ with the reasoning induced by the new information should also be allowed under the original reasoning, without this new information.

As it turns out, the concept of extensive-form rationalizability violates supergame monotonicity with respect to the games $\Gamma$ and $\hat{\Gamma}$ in Figure 1. To see this, consider first the game $\Gamma$ that starts at $h_{2}$. According to extensive-form rationalizability, player 1 , at $h_{3}$, must believe that player 2 's action $d$ is part of an optimal strategy. This is only possible if player 2 would choose $g$ at $h_{4}$. Thus, player 1 must believe at $h_{3}$ that player 2 chooses $g$ at $h_{4}$, and therefore player 1 must choose $e$ at $h_{3}$. Player 2 , anticipating this reasoning by player 1 , will believe at $h_{2}$ that player 1 chooses $e$ at $h_{3}$.

Assume now that player 2 is informed about the fact that player 1 did not choose the outside option $a$ before $h_{2}$ is reached. That is, player 2 learns that the actual game is $\hat{\Gamma}$, starting at $h_{1}$. In line with extensive-form rationalizability, player 2 must believe at $h_{2}$ that choosing $b$ (that is, foregoing the outside option) is part of an optimal strategy for player 1. However, this is only possible if player 2 believes at $h_{2}$ that player 1 will choose $f$ at $h_{3}$, as this is the only way for player 1 to obtain at least as much as by choosing $a$ at the beginning.

As such, with the new information, the only strategy that player 2 can rationally choose in $\Gamma$ is the strategy $(d, g)$. However, this strategy cannot be rationally chosen in $\Gamma$ with the original reasoning, where player 2 believes at $h_{2}$ that player 1 will choose $e$ at $h_{3}$. As such, extensive-form rationalizability violates supergame monotonicity.

Summarizing, we see that in the smaller game $\Gamma$, player 2 must believe at $h_{2}$ that player 1 will choose $e$, whereas in the supergame $\hat{\Gamma}$ player 2 must believe at $h_{2}$ that player 1 will choose $f$. That is, player 2's unique belief at $h_{2}$ is overruled by a new unique belief if player 2 learns about the outside option that player 1 could have chosen before the start of the game $\Gamma$. This contradicts supergame monotonicity.

### 8.2 Subgames and Supergames

To formally define supergame monotonicity, we first define what we mean by a subgame. Consider two dynamic games $\Gamma$ and $\hat{\Gamma}$. Then, $\Gamma$ is a subgame of $\hat{\Gamma}$ if (a) every player in $\Gamma$ is also a player in $\hat{\Gamma}$, (b) every history in $\Gamma$ is also a history in $\hat{\Gamma}$, (c) every terminal history in $\Gamma$ is also a terminal history in $\hat{\Gamma}$, (d) every information set in $\Gamma$ is also an information set in $\hat{\Gamma}$, (e) every information set in $\hat{\Gamma}$ that contains a history in $\Gamma$ must also be an information set in $\Gamma$, (f) every action in $\hat{\Gamma}$ at an information set in $\Gamma$ must also be an action in $\Gamma$ and vice versa, and (g) for every player $i$ in $\Gamma$, the utility function $\hat{u}_{i}$ in $\hat{\Gamma}$, when restricted to the terminal histories in $\Gamma$, coincides with $i$ 's utility function $u_{i}$ in $\Gamma$.

In particular, condition (e) makes sure that a player in $\hat{\Gamma}$, when moving at a history in $\Gamma$, will know that the history at which he is moving is in $\Gamma$. As such, in the larger game $\hat{\Gamma}$ it is common knowledge between all players that are active in $\Gamma$, at each of the histories in $\Gamma$, that the current history is in $\Gamma$. Whenever $\Gamma$ is a subgame of $\hat{\Gamma}$, we say that $\hat{\Gamma}$ is a supergame of $\Gamma$.

### 8.3 Supergame Monotonicity

Recall the intuition behind supergame monotonicity, which states that if a player learns that the game $\Gamma$ was actually preceded by some earlier moves, resulting in a supergame $\hat{\Gamma}$, then this new information should only refine, but never overthrow, his previous reasoning. But what do we mean by the reasoning of a player in the games $\Gamma$ and $\hat{\Gamma}$ ?

Formally, we model the output of the players' reasoning processes by conditional belief vectors, which specify at every information set where this player is active the belief that he holds about the other players' strategies. In general, a dynamic game concept $\varphi$ specifies for every game $\Gamma$ and every player $i$ in $\Gamma$ a set $B_{i}^{\varphi}(\Gamma)$ of conditional belief vectors, representing the possible beliefs that player $i$ can end up with if he reasons according to the standards of $\varphi$.

Now suppose that the players in $\Gamma$ learn that the game was actually preceded by earlier moves, resulting in the supergame $\hat{\Gamma}$. Then, the reasoning of the players in the new, larger game $\hat{\Gamma}$ is represented by the new sets of conditional belief vectors $B_{i}^{\varphi}(\hat{\Gamma})$. But what consequences does this new reasoning have for the choices in the smaller game $\Gamma$ ?

Let us denote by $S_{i}^{\hat{\Gamma}}$ and $S_{i}^{\Gamma}$ the sets of strategies for player $i$ in the games $\hat{\Gamma}$ and $\Gamma$, respectively. Similarly, we denote by $H_{i}^{\hat{\Gamma}}$ and $H_{i}^{\Gamma}$ the collections of information sets in $\hat{\Gamma}$ and $\Gamma$, respectively, where player $i$ is active.

Consider a conditional belief vector $\hat{b}_{i} \in B_{i}^{\varphi}(\hat{\Gamma})$ in the new game $\hat{\Gamma}$ allowed by the new reasoning, an information set $h \in H_{i}^{\Gamma}$ in the subgame, and a strategy $s_{i} \in S_{i}^{\Gamma}(h)$ for player $i$ in the subgame that allows for $h$ to be reached. Then, as we will argue below, we can define the expected utility $u_{i}\left(s_{i}, \hat{b}_{i}(h)\right)$ induced by the strategy $s_{i}$ in the subgame $\Gamma$ and the conditional belief $\hat{b}_{i}(h)$ at $h$ in the supergame $\hat{\Gamma}$.

To see this, consider a strategy $s_{i} \in S_{i}^{\Gamma}(h)$ in the subgame and an opponents' strategy combination $\hat{s}_{-i} \in S_{-i}^{\hat{\Gamma}}(h)$ in the supergame that allows for $h$ to be reached. Then, $\hat{s}_{-i}$ induces an opponents' strategy combination in $\Gamma$, by restricting $\hat{s}_{-i}$ to the information sets in $\Gamma$. Consequently, $\left(s_{i}, \hat{s}_{-i}\right)$ induces a terminal history $z\left(s_{i}, \hat{s}_{-i}\right)$ in $\Gamma$.

Next, consider a strategy $s_{i} \in S_{i}^{\Gamma}(h)$ in the subgame that allows for $h$ to be reached, and a conditional belief $\hat{b}_{i}(h)$ at $h$ in the supergame $\hat{\Gamma}$. The expected utility at $h$, given $s_{i}$ and $\hat{b}_{i}(h)$, is then given by

$$
u_{i}\left(s_{i}, \hat{b}_{i}(h)\right):=\sum_{\hat{s}_{-i} \in S_{-i}^{\hat{R}}(h)} \hat{b}_{i}(h)\left(\hat{s}_{-i}\right) \cdot u_{i}\left(z\left(s_{i}, \hat{s}_{-i}\right)\right) .
$$

We say that the strategy $s_{i}$ is optimal for $\hat{b}_{i}$ at $h$ if

$$
u_{i}\left(s_{i}, \hat{b}_{i}(h)\right) \geq u_{i}\left(s_{i}^{\prime}, \hat{b}_{i}(h)\right) \text { for all } s_{i}^{\prime} \in S_{i}^{\Gamma}(h)
$$

Then, we denote by

$$
S_{i}^{\varphi}(\Gamma \mid \hat{\Gamma}):=\left\{s_{i} \in S_{i}^{\Gamma} \mid s_{i} \text { optimal for some } \hat{b}_{i} \in B_{i}^{\varphi}(\hat{\Gamma}) \text { at all information sets } h \in H_{i}^{\Gamma}\left(s_{i}\right)\right\}
$$

the set of strategies for player $i$ that are optimal in the subgame $\Gamma$ if the players learn that the actual game is $\hat{\Gamma}$.

We call $S_{i}^{\varphi}(\Gamma \mid \hat{\Gamma})$ the set of strategies that is predicted for the subgame $\Gamma$ if the concept $\varphi$ is applied to the supergame $\hat{\Gamma}$. In particular, $S_{i}^{\varphi}(\Gamma \mid \Gamma)$ contains those strategies that the dynamic game concept induces for player $i$ in the game $\Gamma$ if the players do not learn any new information there.

Supergame monotonicity then states that every strategy in $S_{i}^{\varphi}(\Gamma \mid \hat{\Gamma})$, which is allowed by the new reasoning after learning that the actual game is $\hat{\Gamma}$, must also be allowed by the original reasoning which took place before receiving this new information - that is, it must be in $S_{i}^{\varphi}(\Gamma \mid \Gamma)$.

Definition 8.1 (Supergame monotonicity) A dynamic game concept $\varphi$ satisfies supergame monotonicity if for every dynamic game $\Gamma$, every supergame $\hat{\Gamma}$, and every player $i$, it holds that $S_{i}^{\varphi}(\Gamma \mid \hat{\Gamma}) \subseteq S_{i}^{\varphi}(\Gamma \mid$ $\Gamma)$.

In general terms, supergame monotonicity thus states that every "solution" of the supergame, when restricted to the small game, should also be a "solution" of the small game itself. When read in this fashion, this property corresponds precisely to requirement BI1 in Kohlberg and Mertens (1986), which states that a solution of a game should always induce a solution in each of its subgames.

Kohlberg and Mertens use condition BI1 as a key characteristic of any backward induction concept. As such, supergame monotonicity can be viewed as a necessary condition for backward induction reasoning. We have seen above that the concept of extensive-form rationalizability violates supergame monotonicity, which confirms that this concept is not based on backward induction reasoning.

### 8.4 Forward and Backward Rationalizability

It can be shown that the new concept proposed in this paper satisfies supergame monotonicity. In light of the discussion above, this indicates that the concept of forward and backward rationalizability is compatible with Kohlberg and Mertens' backward induction property BI1.

Theorem 8.1 (Supergame monotonicity) The concept of forward and backward rationalizability satisfies supergame monotonicity.

In Figure 1 let, as before, $\Gamma$ be the game that starts at $h_{2}$ and $\hat{\Gamma}$ the supergame that starts at $h_{1}$. Then, by construction, the strategies $S_{i}^{\varphi}(\Gamma \mid \hat{\Gamma})$ that the forward and backward rationalizability procedure selects for the subgame $\Gamma$ if the players learn that the actual game is $\hat{\Gamma}$ are the unique backward induction strategies in $\Gamma$. These, in turn, correspond to the strategies that are selected when the procedure is applied to $\Gamma$ alone. As such, the reasoning of both players within $\Gamma$ is not altered if we move from $\Gamma$ to the supergame $\hat{\Gamma}$. In particular, supergame monotonicity holds for the concept of forward and backward rationalizability when moving from $\Gamma$ to $\hat{\Gamma}$.

There are also examples where the additional information of past play, provided by the supergame $\hat{\Gamma}$, may strictly refine the reasoning of the players when using forward and backward rationalizability. Consider, for instance, Figure 2, where we focus on the game $\Gamma$ that starts at $h_{3}$ and the supergame $\hat{\Gamma}$ starting at $h_{2}$. It is easily seen that forward and backward rationalizability allows for all possible choices in $\Gamma$ if the concept is applied to $\Gamma$ alone. If the players learn that the actual game is $\hat{\Gamma}$, then player 1 must believe at $h_{3}$ that
player 2 chooses the strategy $(c, h)$. Therefore, the concept selects for player 1 only the strategy $f$ and for player 2 only the strategy $h$ in $\Gamma$. Thus, the additional information about player 2's past play provided by the supergame $\hat{\Gamma}$ strictly refines the reasoning of player 1 within the original game $\Gamma$.

### 8.5 Relation with Extensive Form Rationalizability Conditional on Subgames

When taken together, Theorems 6.3 and 8.1 imply the following property: Consider a game $\Gamma$ embedded in a supergame $\hat{\Gamma}$. Suppose the players learn that the actual game being played is $\hat{\Gamma}$, and concentrate on the outcomes that the forward and backward rationalizability procedure selects for the subgame $\Gamma$. Then, every such outcome will also be possible if extensive-form rationalizability is applied to the subgame $\Gamma$ only. ${ }^{11}$

To see why this holds, let us denote by $f b r$ the dynamic game concept associated with forward and backward rationalizability. Take a strategy profile $\left(s_{i}\right)_{i \in I}$ in the subgame $\Gamma$, where $s_{i} \in S_{i}^{f b r}(\Gamma \mid \hat{\Gamma})$ for every player $i$, resulting in an outcome $z$ in $\Gamma$. Since, by Theorem 8.1 , our procedure satisfies supergame monotonicity, we must have that $s_{i} \in S_{i}^{f b r}(\Gamma \mid \Gamma)$ for every player $i$. Hence, the outcome $z$ is also possible if $f b r$ is applied to $\Gamma$ only. But then, by Theorem 6.3 applied to the smaller game $\Gamma$, the outcome $z$ must also be possible if extensive-form rationalizability is applied to $\Gamma$ only.

In the statement below, let $f b r$ and $e f r$ refer to the forward and backward rationalizability concept, and the extensive-form rationalizability concept, respectively.

Corollary 8.1 (Forward induction conditional on subgames) Let the game $\Gamma$ be embedded in a supergame $\hat{\Gamma}$. Then, $Z\left(S^{f b r}(\Gamma \mid \hat{\Gamma})\right) \subseteq Z\left(S^{e f r}(\Gamma \mid \Gamma)\right)$.

That is, conditional on reaching a subgame our procedure refines, in terms of outcomes, the extensiveform rationalizability procedure applied to this subgame alone. As an illustration, consider the double outside option game in Figure 2. Let $\hat{\Gamma}$ be the whole game, and $\Gamma$ the subgame that starts at $h_{3}$. If we apply the forward and backward rationalizability procedure to $\hat{\Gamma}$, then the predicted strategies conditional on $\Gamma$ would be $f$ for player 1 and $h$ for player 2 . Hence, the unique predicted outcome conditional on $\Gamma$ would be $(f, h)$. On the other hand, if extensive-form rationalizability would be applied to $\Gamma$ alone, then every outcome in $\Gamma$ would be possible.

### 8.6 Backwards Rationalizability

Now turn to the concept of backwards rationalizability, which provides an instance of pure backward induction reasoning. It turns out that this concept also satisfies supergame monotonicity. However, different from the concept of forward and backward rationalizability, it always satisfies supergame monotonicity with equality. That is, if we move from a game $\Gamma$ to a supergame $\hat{\Gamma}$, then the strategies selected by backwards rationalizability in the game $\hat{\Gamma}$ conditional on reaching the subgame $\Gamma$ will be exactly the same as when we would apply backwards rationalizability to the smaller game $\Gamma$ only.

[^11]In other words, the additional information provided by the supergame $\hat{\Gamma}$ does not alter the reasoning of the players at information sets within $\Gamma$. In particular, it does not refine the reasoning of the players: They take the additional information about past play for granted, but do not incorporate this information in their reasoning process. This is typical of pure backward induction reasoning.

In the statement below, $b r$ refers to the backwards rationalizability concept.
Theorem 8.2 (Supergame monotonicity with equality) Let the game $\Gamma$ be embedded in a supergame $\hat{\Gamma}$. Then, for every player $i$ we have that $S_{i}^{b r}(\Gamma \mid \hat{\Gamma})=S_{i}^{b r}(\Gamma \mid \Gamma)$.

The strong property in Theorem 8.2, which states that supergame monotonicity must be satisfied "with equality", corresponds to the combination of the backward induction properties BI1 and BI2 in Kohlberg and Mertens (1986). Their condition BI2 states that a solution of a subgame should also be part of a solution of the larger game it belongs to.

Kohlberg and Mertens insist on condition BI1, but reject condition BI2, as it precludes forward induction reasoning. This is precisely the reason why our concept of forward and backward rationalizability, which combines forward and backward induction reasoning, satisfies condition BI1 but violates condition BI2.

To see the latter, consider Figure 2, and let $\Gamma$ be the game that starts at $h_{3}$. Then, forward and backward rationalizability allows for all possible choices there. Now, move to the supergame $\hat{\Gamma}$ that starts at $h_{1}$. Then, we have seen that the predicted strategies conditional on $\Gamma$ only involve the choices $f$ and $h$. As such, forward and backward rationalizability violates condition BI2, and therefore does not satisfy supergame monotonicity with equality.

The reason is clear: Condition BI2 states that when the player discovers that the actual game being played is the supergame $\hat{\Gamma}$, and not $\Gamma$, then the player should ignore the additional information provided by $\hat{\Gamma}$ in his reasoning process. This goes against the whole idea of forward induction which is present, for instance, in forward and backward rationalizability.

In Theorem 5.1 we have seen that forward and backward rationalizability provides a refinement of backwards rationalizability in terms of strategies. It is not hard to show that this result also holds conditional on every subgame. To see this, consider a subgame $\Gamma$ within a supergame $\hat{\Gamma}$. Then, we know by Theorem 8.1 that every strategy $s_{i} \in S_{i}^{f b r}(\Gamma \mid \hat{\Gamma})$ is also in $s_{i} \in S_{i}^{f b r}(\Gamma \mid \Gamma)$. Moreover, by applying Theorem 5.1 to the smaller game $\Gamma$ we know that $s_{i} \in S_{i}^{b r}(\Gamma \mid \Gamma)$. That is, the strategy $s_{i}$ is backwards rationalizable in the subgame $\Gamma$. We thus arrive at the conclusion below, where $f b r$ and $b r$ refer to the forward and backward rationalizability concept, and the backwards rationalizability concept, respectively.

Corollary 8.2 (Backward induction conditional on subgames) Let the game $\Gamma$ be embedded in a supergame $\hat{\Gamma}$. Then, for every player $i$ we have that $S_{i}^{f b r}(\Gamma \mid \hat{\Gamma}) \subseteq S_{i}^{b r}(\Gamma \mid \Gamma)$.

In view of Corollaries 8.1 and 8.2 we thus conclude that the forward and backward rationalizability procedure, conditional on every subgame, (a) provides a refinement, in terms of outcomes, of extensiveform rationalizability applied to this subgame, and (b) provides a refinement, in terms of strategies, of backwards rationalizability applied to this subgame. In particular, forward and backward rationalizability,
conditional on every subgame, will always weakly refine the outcomes that are induced by both extensiveform rationalizability and backwards rationalizability. That is, we obtain the following result.

Corollary 8.3 Let the game $\Gamma$ be embedded in a supergame $\hat{\Gamma}$. Then,

$$
Z\left(S^{f b r}(\Gamma \mid \hat{\Gamma})\right) \subseteq Z\left(S^{b r}(\Gamma \mid \Gamma)\right) \cap Z\left(S^{e f r}(\Gamma \mid \Gamma)\right)
$$

As a consequence, our concept will always be in line with forward and backward induction reasoning, even upon reaching unexpected subgames.

## 9 Appendix

### 9.1 Proof of Section 3

To prove Theorem 3.1 we need the following result.
Lemma 9.1 (Strong belief of nested sets) For a given player $i$ let

$$
\emptyset \neq D_{k} \subseteq D_{k-1} \subseteq \ldots \subseteq D_{0}=S_{-i}
$$

be a sequence of nested subsets of opponents' strategy combinations. Then, there is a conditional belief vector $b_{i} \in B_{i}$ that strongly believes each of the sets $D_{k}, D_{k-1}, \ldots, D_{0}$.

Proof. Take some arbitrary probability distribution $p_{i} \in \Delta\left(S_{-i}\right)$ such that $p_{i}\left(s_{-i}\right)>0$ for all $s_{-i} \in S_{-i}$. For a given information set $h \in H_{i}$ let $m(h)$ be the highest number in $\{0, \ldots, k\}$ such that $S_{-i}(h) \cap D_{m(h)} \neq \emptyset$. Define the conditional belief $b_{i}(h)$ by

$$
b_{i}(h)\left(s_{-i}\right):=\left\{\begin{aligned}
\frac{p_{i}\left(s_{-i}\right)}{p_{i}\left(S_{-i}(h) \cap D_{m(h)}\right)}, & \text { if } s_{-i} \in S_{-i}(h) \cap D_{m(h)} \\
0, & \text { otherwise }
\end{aligned}\right.
$$

Then, it may be verified that the conditional belief vector $b_{i}=\left(b_{i}(h)\right)_{h \in H_{i}}$ so constructed satisfies Bayesian updating, and strongly believes each of the sets $D_{k}, D_{k-1}, \ldots, D_{0}$.

Proof of Theorem 3.1. Recall that $B_{i}^{m . k}$ and $S_{i}^{m . k}$ are the sets of conditional belief vectors and strategies, respectively, that survive round $k$ at period $m$ of the forward and backward rationalizability procedure. We show, by induction on $m . k$, that $B_{i}^{m . k}$ and $S_{i}^{m . k}$ are always non-empty, starting with M.0.

By definition, $B_{i}^{M .0}=B_{i}$ and $S_{i}^{M .0}=S_{i}$. Applying Lemma 9.1 to the case $D_{k}=D_{0}=S_{-i}$ shows that $B_{i}$ is non-empty.

Now, suppose that $m$ and $k$ are such that $(m . k) \neq(M .0)$. We distinguish two cases: (1) $k \geq 1$, and (2) $k=0$.

Case 1. Suppose that $k \geq 1$. Then, by definition, $B_{i}^{m . k}=\left\{b_{i} \in B_{i}^{m . k-1} \mid b_{i}\right.$ strongly believes $\left.S_{-i}^{m . k-1}\right\}$. By construction,

$$
S_{-i}^{m . k-1} \subseteq S_{-i}^{m \cdot k-2} \subseteq \ldots \subseteq S_{-i}^{M .0}
$$

and $B_{i}^{m . k}$ consists of all those conditional belief vectors that strongly believe each of these nested sets. As, by the induction assumption, each of these nested sets is non-empty, it follows by Lemma 9.1 that $B_{i}^{m . k}$ is non-empty as well.

Now, take some $b_{i} \in B_{i}^{m . k}$. Then, $b_{i}$ satisfies Bayesian updating. It follows from Lemma 8.13.2 in Perea (2012) that there is a strategy $s_{i}$ that is optimal for $b_{i}$ at all $h \in H_{i}\left(s_{i}\right)$. In particular, $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards, and hence $s_{i}$ is in $S_{i}^{m, k}$. Thus, $S_{i}^{m . k}$ is non-empty.
Case 2. Suppose that $k=0$. Then, by construction, $B_{i}^{m .0}=B_{i}^{m+1 . K_{m+1}}$ and $S_{i}^{m .0}=S_{i}^{m+1 . K_{m+1}}$, where $K_{m+1}$ is the round at which the procedure at period $m+1$ terminates. By the induction assumption, $B_{i}^{m+1 . K_{m+1}}$ and $S_{i}^{m+1 . K_{m+1}}$ are non-empty, and thus $B_{i}^{m .0}$ and $S_{i}^{m .0}$ are non-empty as well.

It thus follows, by induction on $m$ and $k$, that $S_{i}^{m . k}$ and $B_{i}^{m . k}$ are non-empty for every $m$ and $k$, and for every player $i$. As the procedure terminates after finitely many rounds, we conclude that every player $i$ has at least one strategy and one conditional belief vector that are forward and backward rationalizable.

### 9.2 Proofs of Section 4

Proof of Lemma 4.1. Consider some information set $h \in H_{i}$ of player $i$ and let $s_{i} \in S_{i}(h)$ be a strategy that allows $h$ to be reached. We first show that the set of types $T_{i}\left(s_{i}, h\right)$ of player $i$ for whom playing $s_{i}$ is optimal at $h$ is a closed set of types. To this purpose, we consider for any alternative strategy $r_{i} \in S_{i}(h)$, any opponents' strategy combination $s_{-i}$ and any opponents' type combination $t_{-i}$ the utility difference

$$
u_{i}\left(s_{i}, s_{-i}, t_{-i}\right)-u_{i}\left(r_{i}, s_{-i}, t_{-i}\right):=u_{i}\left(z\left(s_{i}, s_{-i}\right)\right)-u_{i}\left(z\left(r_{i}, s_{-i}\right)\right) .
$$

By fixing $s_{i}, r_{i}$, and $h$, and varying $s_{-i}$ and $t_{-i}$, we obtain a bounded continuous function

$$
u_{i}\left(s_{i}, \cdot, \cdot\right)-u_{i}\left(r_{i}, \cdot, \cdot\right): S_{-i}(h) \times T_{-i} \rightarrow \mathbf{R} .
$$

This is indeed the case, since we endow $S_{-i}(h)$ with the discrete topology and $u_{i}\left(s_{i}, s_{-i}, t_{-i}\right)-u_{i}\left(r_{i}, s_{-i}, t_{-i}\right)$ only depends on the $S_{-i}$-dimension of $S_{-i} \times T_{-i}$. Hence, the set of measures $\mu_{i} \in \Delta\left(S_{-i}(h) \times T_{-i}\right)$ such that integrating over this function with respect to $\mu_{i}$ is non-negative is a closed set of measures, which we call $\Delta\left(S_{-i}(h) \times T_{-i}\right)^{s_{i} \geq r_{i}}$. The set of measures $\mu_{i} \in \Delta\left(S_{-i}(h) \times T_{-i}\right)$ such that $s_{i}$ is optimal at $h$ is the intersection

$$
\Delta\left(S_{-i}(h) \times T_{-i}\right)^{s_{i}, h}:=\bigcap_{r_{i} \in S_{i}(h)} \Delta\left(S_{-i}(h) \times T_{-i}\right)^{s_{i} \geq r_{i}},
$$

which is closed as well. Note that, by construction,

$$
T_{i}\left(s_{i}, h\right)=\left\{t_{i} \in T_{i} \mid \beta_{i}\left(t_{i}, h\right) \in \Delta\left(S_{-i}(h) \times T_{-i}\right)^{s_{i}, h}\right\} .
$$

Since the mapping $\beta_{i}(\cdot, h): T_{i} \rightarrow \Delta\left(S_{-i}(h) \times T_{-i}\right)$ is continuous, we conclude that the set $T_{i}\left(s_{i}, h\right)$ is closed.
Recall that the set of types $t_{i}$ such that $s_{i}$ is optimal at $h$ is precisely $T_{i}\left(s_{i}, h\right)$. For a given period $m$, let $H^{\geq m}:=H^{m} \cup H^{m+1} \cup \ldots \cup H^{M}$ be the collection of information sets from period $m$ onwards. Then, the set of types for which $s_{i}$ is optimal from period $m$ onwards is

$$
T_{i}^{\geq m}\left(s_{i}\right):=\bigcap_{h \in H_{i}\left(s_{i}\right) \cap H \geq m} T_{i}\left(s_{i}, h\right),
$$

which is closed in $T_{i}$. Note that if $s_{i}$ does not reach any information set in $H^{\geq m}$, then $s_{i}$ is automatically optimal from period $m$ onwards for all types in $T_{i}$. For each of the finitely many strategies $s_{i} \in S_{i}$ of player $i$, the set $\left\{s_{i}\right\} \times T_{i}^{\geq m}\left(s_{i}\right)$ is closed in the product topology of $S_{i} \times T_{i}$, since it is the product of two closed sets. The set

$$
\left(S_{i} \times T_{i}\right)^{r a t, m}=\bigcup_{s_{i} \in S_{i}}\left(\left\{s_{i}\right\} \times T_{i}^{\geq m}\left(s_{i}\right)\right)
$$

is closed in $S_{i} \times T_{i}$ since it is the union of finitely many closed sets. If $\hat{T}_{i}$ is a measurable subset of $T_{i}$ then $\left(S_{i} \times \hat{T}_{i}\right)^{r a t, m}=\left(S_{i} \times T_{i}\right)^{r a t, m} \cap\left(S_{i} \times \hat{T}_{i}\right)$ is measurable since it is an intersection of a closed and a measurable set. If $\hat{T}_{i}$ is closed, then $S_{i} \times \hat{T}_{i}$ is closed and hence $\left(S_{i} \times \hat{T}_{i}\right)^{r a t, m}$ is closed, being the intersection of two closed sets.

Proof of Lemma 4.2. We start by proving the following result.
Claim. Let $E$ be a closed subset of $S_{-i} \times T_{-i}$. Then, the set $\left\{t_{i} \mid t_{i}\right.$ strongly believes $\left.E\right\}$ is a closed subset of $T_{i}$.
Proof of claim. Let $h \in H_{i}$ be such that $\left(S_{-i}(h) \times T_{-i}\right) \cap E \neq \emptyset$. We show that the set of measures in $\Delta\left(S_{-i}(h) \times T_{-i}\right)$ that assign probability 1 to $E$ is closed set. To this end, let $\left(\mu_{n}\right)_{n \in \mathbb{N}} \rightarrow \mu$ be a sequence of probability measures in $\Delta\left(S_{-i}(h) \times T_{-i}\right)$ converging to $\mu \in \Delta\left(S_{-i}(h) \times T_{-i}\right)$ such that $\mu_{n}(E)=1$ for all $n \in \mathbb{N}$. We have to show that $\mu(E)=1$. But this follows immediately from the Portemanteau Theorem (Kechris (1995), Theorem 17.20). By continuity, the set $\left\{t_{i} \in T_{i} \mid \beta_{i}\left(t_{i}, h\right)(E)=1\right\}$ is a closed set of types. The set of types $t_{i}$ that strongly believe $E$ is the finite intersection of such sets of types over all $h \in H_{i}$ such that $\left(S_{-i}(h) \times T_{-i}\right) \cap E \neq \emptyset$. Hence, this is a closed set of types. $\diamond$

The lemma now follows immediately by iteratively applying the claim and Lemma 4.1.
Proof of Theorem 4.1. As a first step we will use the forward and backward rationalizability procedure to build a finite type space. Later we will use this model to prove the theorem. Moreover, we will make sure that the type space is non-reduntant, that is, no two different types of a player induce the same conditional belief hierarchy.

Recall that, for every player $i$, period $m$, and round $k$, the sets $B_{i}^{m . k}$ and $S_{i}^{m . k}$ are the collections of conditional belief vectors and strategies, respectively, selected by the forward and backward rationalizability procedure at round $k$ of period $m$. In particular, $B_{i}^{L \cdot K_{L}}$ and $S_{i}^{L . K_{L}}$ are the sets of conditional belief hierarchies and strategies, respectively, that survive all rounds at all periods.

For every player $i$ and strategy $s_{i} \in S_{i}^{L . K_{L}}$ choose a conditional belief vector $b_{i}\left[s_{i}\right] \in B_{i}^{L . K_{L}}$ such that $s_{i}$ is optimal for $b_{i}\left[s_{i}\right]$ from the first period onwards.

For all other strategies $s_{i}$ there is a period $m \in\{L, \ldots, M\}$ and a round $k$ such that $s_{i} \in S_{i}^{m . k} \backslash S_{i}^{m . k+1}$. For such a strategy $s_{i} \in S_{i}^{m . k} \backslash S_{i}^{m . k+1}$ we can then choose a conditional belief vector $b_{i}\left[s_{i}\right] \in B_{i}^{m . k}$ such that $s_{i}$ is optimal for $b_{i}\left[s_{i}\right]$ from period $m$ onwards if $k \geq 1$, and $s_{i}$ is optimal from period $m+1$ onwards if $k=0$. If $m . k=M .0$, then optimality from period $M+1$ onwards means that $s_{i}$ need not be optimal for $b_{i}\left[s_{i}\right]$ at all.

Based on these conditional belief vectors $b_{i}\left[s_{i}\right]$ we will now construct a finite type space $\hat{\mathcal{T}}=\left(\left(T_{i}, \mathcal{O}_{i}\right), \beta_{i}\right)$ where the sets of types are given by $T_{i}=\left\{t_{i}^{b_{i}\left[s_{i}\right]} \mid s_{i} \in S_{i}\right\}$, and the belief mappings $\beta_{i}$ are such that

$$
\beta_{i}\left(t_{i}^{b_{i}\left[s_{i}\right]}, h\right)\left(\left(s_{j}, t_{j}\right)_{j \neq i}\right)=\left\{\begin{array}{cl}
b_{i}\left[s_{i}\right](h)\left(\left(s_{j}\right)_{j \neq i}\right), & \text { if } t_{j}=t_{j}^{b_{j}\left[s_{j}\right]} \text { for all } j \neq i  \tag{9.1}\\
0, & \text { otherwise }
\end{array}\right.
$$

for all players $i$, all strategies $s_{i}$, all information sets $h \in H_{i}$, and all opponents' strategy-type combinations $\left(s_{j}, t_{j}\right)_{j \neq i} \in S_{-i} \times T_{-i}$. Hence, every type $t_{i}^{b_{i}\left[s_{i}\right]}$ has the belief $b_{i}\left[s_{i}\right](h)$ about the opponents' strategy combinations at every information set $h \in H_{i}$, and matches, in its belief, every opponent's strategy $s_{j}$ with the associated type $t_{j}^{b_{j}\left[s_{j}\right]}$. It is easy to see that every type in this model satisfies Bayesian updating. Note that $b_{i}\left[s_{i}\right]=b_{i}\left[\hat{s}_{i}\right]$ implies that $t_{i}^{b_{i}\left[s_{i}\right]}=t_{i}^{b_{i}\left[\hat{s}_{i}\right]}$, and hence the type space $\hat{\mathcal{T}}$ is non-redundant by construction.

For every player $i$ and conditional belief vector $b_{i} \in B_{i} \backslash\left\{b_{i}\left[s_{i}\right] \mid s_{i} \in S_{i}\right\}$ not present in $\hat{\mathcal{T}}$, we add a new type $t_{i}^{b_{i}}$ to $\hat{\mathcal{T}}$ whose conditional beliefs are given by

$$
\beta_{i}\left(t_{i}^{b_{i}}, h\right)\left(\left(s_{j}, t_{j}\right)_{j \neq i}\right)=\left\{\begin{align*}
b_{i}(h)\left(\left(s_{j}\right)_{j \neq i}\right), & \text { if } t_{j}=t_{j}^{b_{j}\left[s_{j}\right]} \text { for all } j \neq i  \tag{9.2}\\
0, & \text { otherwise }
\end{align*}\right.
$$

The new type space obtained after adding the type $t_{i}^{b_{i}}$ to $\hat{\mathcal{T}}$ is denoted by $\hat{\mathcal{T}} \cup\left\{t_{i}^{b_{i}}\right\}$.
Let $\mathcal{T}$ be a universal type space. Then, by definition, each of the finite type spaces $\hat{\mathcal{T}}$ and $\hat{\mathcal{T}} \cup\left\{t_{i}^{b_{i}}\right\}$ maps in a unique way to the universal type space $\mathcal{T}$ by a type morphism. Note that for every type $t_{i}^{b_{i}\left[s_{i}\right]}$ in $\hat{\mathcal{T}}$ the induced conditional belief hierarchy is the same, no matter whether it is regarded as a type in $\hat{\mathcal{T}}$ or a type in $\hat{\mathcal{T}} \cup\left\{t_{j}^{b j}\right\}$. Since a type morphism always preserves the induced conditional belief hierarchy, the type $t_{i}^{b_{i}\left[s_{i}\right]}$ will be mapped to the same type in the universal type space $\mathcal{T}$, no matter whether it is regarded as a type in $\hat{\mathcal{T}}$ or a type in $\hat{\mathcal{T}} \cup\left\{t_{j}^{b_{j}}\right\}$. As each of the type spaces $\hat{\mathcal{T}}$ and $\hat{\mathcal{T}} \cup\left\{t_{i}^{b_{i}}\right\}$ is non-redundant, every type in these type spaces may be uniquely identified with a type in the universal type space $\mathcal{T}$.

For every player $i$, period $m$ and number $k \in\{0,1, \ldots\}$, we denote by $T_{i}^{m . k}$ the set of types for player $i$ in the universal type space $\mathcal{T}$ that express $k$-fold backward strong belief in rationality from period $m$ onwards. Define

$$
\hat{B}_{i}^{m . k}:=\left\{b_{i} \in B_{i} \mid \text { there is some } t_{i} \in T_{i}^{m \cdot k} \text { that induces the conditional belief vector } b_{i}\right\}
$$

and

$$
\hat{S}_{i}^{m \cdot k}:=\left\{s_{i} \in S_{i} \mid \text { there is some } t_{i} \in T_{i}^{m \cdot k} \text { with }\left(s_{i}, t_{i}\right) \in\left(S_{i} \times T_{i}^{m \cdot k}\right)^{r a t, m}\right\} .
$$

Here, when we say that " $t_{i}$ induces the conditional belief vector $b_{i}$ ", we mean that $\operatorname{marg}_{S_{-i}(h)} \beta_{i}\left(t_{i}, h\right)=$ $b_{i}(h)$ for every $h \in H_{i}$. We prove the following result.

Claim. For every period $m$ and number $k \in\{0,1, \ldots\}$ it holds that (i) $\hat{B}_{i}^{m . k} \subseteq B_{i}^{m . k+1}$, (ii) $B_{i}^{m . k+1} \subseteq \hat{B}_{i}^{m . k}$ and for every $b_{i} \in B_{i}^{m \cdot k+1}$ we have that $t_{i}^{b_{i}} \in T_{i}^{m . k}$, (iii) $\hat{S}_{i}^{m \cdot k} \subseteq S_{i}^{m \cdot k+1}$ and (iv) $S_{i}^{m \cdot k+1} \subseteq \hat{S}_{i}^{m \cdot k}$.

Proof of claim. We show the four statements by induction on m.k.
We start with M.0. Then, $\hat{B}_{i}^{M .0}$ is, by definition, the set of conditional belief vectors induced by the types in $T_{i}^{M .0}$. As $T_{i}^{M .0}=T_{i}$, this is the set of all conditional belief vectors, and hence $\hat{B}_{i}^{M .0}=B_{i}$. As, by construction, $B_{i}^{M .1}=B_{i}$ as well, it follows that $\hat{B}_{i}^{M .0}=B_{i}^{M .1}$. Moreover, as $T_{i}^{M .0}=T_{i}$, for every $b_{i} \in B_{i}^{M .1}$ we have that $t_{i}^{b_{i}} \in T_{i}^{M .0}$. This establishes (i) and (ii).

Moreover, $\hat{S}_{i}^{M .0}$ contains precisely those strategies that are optimal from period $M$ onwards for some $t_{i} \in T_{i}^{M .0}$. As $T_{i}^{M .0}=T_{i}$, these are precisely the strategies that are optimal from period $M$ onwards for some conditional belief vector $b_{i} \in B_{i}$. By definition, these are precisely the strategies in $S_{i}^{M .1}$. Hence, we conclude that $\hat{S}_{i}^{M .0}=S_{i}^{M .1}$. This establishes (iii) and (iv).

Next, take some $m . k \neq M .0$, and assume that the claim holds for $m . k-1$ if $k \geq 1$, and that the claim holds for any $m+1 . k^{\prime}$ if $k=0$. We distinguish two cases: (1) $k=0$, and (2) $k \geq 1$.
Case 1. Suppose that $k=0$. Then, by definition, there is some round $K$ such that $\hat{B}_{i}^{m .0}=\hat{B}_{i}^{m+1 . K}$ and $B_{i}^{m .1}=B_{i}^{m+1 . K+1}$. As, by the induction assumption, $\hat{B}_{i}^{m+1 . K}=B_{i}^{m+1 . K+1}$, we conclude that $\hat{B}_{i}^{m .0}=B_{i}^{m .1}$. Moreover, by construction, $\hat{S}_{i}^{m .0}$ is the set of strategies that are optimal, from period $m$ onwards, for some $b_{i} \in \hat{B}_{i}^{m .0}$, whereas $S_{i}^{m .1}$ is the set of strategies that are optimal, from period $m$ onwards, for some $b_{i} \in B_{i}^{m .1}$. Since $\hat{B}_{i}^{m .0}=B_{i}^{m .1}$, it follows that $\hat{S}_{i}^{m .0}=S_{i}^{m .1}$.
Case 2. Suppose that $k \geq 1$.
(i) We show that $\hat{B}_{i}^{m . k} \subseteq B_{i}^{m . k+1}$. Take some $b_{i} \in \hat{B}_{i}^{m . k}$. Then, there is some $t_{i} \in T_{i}^{m . k}$ that induces $b_{i}$. By definition, $T_{i}^{m . k} \subseteq T_{i}^{m \cdot k-1}$, and hence $b_{i} \in \hat{B}_{i}^{m \cdot k-1}$. By the induction assumption on (i) it follows that $b_{i} \in B_{i}^{m . k}$. Hence, we only need to show that $b_{i}$ strongly believes $S_{-i}^{m . k}$. Let $h \in H_{i}$ be such that $S_{-i}^{m . k} \cap S_{-i}(h) \neq \emptyset$. We must show that $b_{i}(h)\left(S_{-i}^{m . k}\right)=1$. By the induction assumption applied to (iii) and (iv) we know that $S_{-i}^{m \cdot k}=\hat{S}_{-i}^{m \cdot k-1}$. Hence, by the definition of $\hat{S}_{j}^{m . k-1}$ for every $j \neq i$, we know that $\times_{j \neq i}\left(S_{j} \times T_{j}^{m . k-1}\right)^{r a t, m} \cap\left(S_{-i}(h) \times T_{-i}\right) \neq \emptyset$. Therefore, since $t_{i} \in T_{i}^{m . k}$, we conclude that $\beta_{i}\left(t_{i}, h\right)\left(\times_{j \neq i}\left(S_{j} \times\right.\right.$ $\left.\left.T_{j}^{m \cdot k-1}\right)^{r a t, m}\right)=1$. This, in turn, implies that $b_{i}(h)\left(\hat{S}_{-i}^{m \cdot k-1}\right)=1$. As, by the induction assumption on (iii) and (iv), $S_{-i}^{m . k}=\hat{S}_{-i}^{m . k-1}$, we conclude that $b_{i}(h)\left(S_{-i}^{m . k}\right)=1$. Hence, $b_{i}$ strongly believes $S_{-i}^{m . k}$. Since $b_{i} \in B_{i}^{m . k}$, it follows that $b_{i} \in B_{i}^{m . k+1}$. As such, $\hat{B}_{i}^{m . k} \subseteq B_{i}^{m . k+1}$.
(ii) We show that $B_{i}^{m \cdot k+1} \subseteq \hat{B}_{i}^{m \cdot k}$ and for every $b_{i} \in B_{i}^{m \cdot k+1}$ we have that $t_{i}^{b_{i}} \in T_{i}^{m . k}$. Take some $b_{i} \in B_{i}^{m . k+1}$. Then, in particular, $b_{i} \in B_{i}^{m . k}$ and hence we know, by the induction assumption on (ii), that $t_{i}^{b_{i}} \in T_{i}^{m . k-1}$. Thus, to prove that $t_{i}^{b_{i}} \in T_{i}^{m . k}$ it only remains to show that $t_{i}^{b_{i}}$ strongly believes $\times_{j \neq i}\left(S_{j} \times T_{j}^{m . k-1}\right)^{\text {rat.m. }}$. To this end, let $h \in H_{i}$ be such that $\left(S_{-i}(h) \times T_{-i}\right) \cap\left(\times_{j \neq i}\left(S_{j} \times T_{j}^{m . k-1}\right)^{r a t, m}\right) \neq \emptyset$. We must show that $\beta_{i}\left(t_{i}^{b_{i}}, h\right)\left(\times_{j \neq i}\left(S_{j} \times T_{j}^{m \cdot k-1}\right)^{r a t, m}\right)=1$.

By definition, $\hat{S}_{-i}^{m . k-1}=\operatorname{proj}_{S_{-i}}\left(\times_{j \neq i}\left(S_{j} \times T_{j}^{m . k-1}\right)^{r a t, m}\right)$. Note that by the induction assumption of (iii) and (iv) we have that $\hat{S}_{-i}^{m \cdot k-1}=S_{-i}^{m \cdot k}$. Therefore, we have $S_{-i}(h) \cap S_{-i}^{m \cdot k} \neq \emptyset$. Since $b_{i} \in B_{i}^{m \cdot k+1}$ it follows that $b_{i}(h)\left(S_{-i}^{m_{i} k}\right)=1$, and hence $b_{i}(h)\left(\hat{S}_{-i}^{m \cdot k-1}\right)=1$. By the definition of $t_{i}^{b_{i}}$ in (9.2) we have $\beta_{i}\left(t_{i}^{b_{i}}, h\right)\left(\left(\hat{S}_{-i}^{m . k-1} \cap S_{-i}(h)\right) \times T_{-i}\right)=1$, and that $\beta_{i}\left(t_{i}, h\right)$ assigns probability 1 to the set of opponents' strategy-type combinations $\left\{\left(s_{j}, t_{j}^{b_{j}\left[s_{j}\right]}\right)_{j \neq i} \mid s_{j} \in \hat{S}_{j}^{m . k-1}\right.$ for all $\left.j \neq i\right\}$. As $\hat{S}_{-i}^{m . k-1}=S_{-i}^{m . k}$ we conclude that $\beta_{i}\left(t_{i}^{b_{i}}, h\right)$ assigns probability 1 to the set of opponents' strategy-type combinations $\left\{\left(s_{j}, t_{j}^{b_{j}\left[s_{j}\right]}\right)_{j \neq i} \mid s_{j} \in S_{j}^{m . k}\right.$ for all $j \neq i\}$.

Consider a type $t_{j}^{b_{j}\left[s_{j}\right]}$ where $s_{j} \in S_{j}^{m . k}$. Then, we know by the definition of type $t_{j}^{b_{j}\left[s_{j}\right]}$ in (9.1) that $t_{j}^{b_{j}\left[s_{j}\right]}$ induces the conditional belief vector $b_{j}\left[s_{j}\right] \in B_{j}^{m . k}$, and that $s_{j}$ is optimal for $b_{j}\left[s_{j}\right]$ from period $m$ onwards. Hence, $s_{j}$ is optimal for $t_{j}^{b_{j}\left[s_{j}\right]}$ from period $m$ onwards. As $b_{j}\left[s_{j}\right] \in B_{j}^{m . k}$ we conclude by the induction assumption of (ii) that $t_{j}^{b_{j}\left[s_{j}\right]} \in T_{j}^{m . k-1}$. As $s_{j}$ is optimal for type $t_{j}^{b_{j}\left[s_{j}\right]}$ from period $m$ onwards, it follows that $\left(s_{j}, t_{j}^{b_{j}\left[s_{j}\right]}\right) \in\left(S_{j} \times T_{j}^{m . k-1}\right)^{r a t, m}$. Recall that $\beta_{i}\left(t_{i}^{b_{i}}, h\right)$ assigns probability 1 to the set of opponents' strategy-type combinations $\left\{\left(s_{j}, t_{j}^{b_{j}\left[s_{j}\right]}\right)_{j \neq i} \mid s_{j} \in S_{j}^{m . k}\right.$ for all $\left.j \neq i\right\}$. Hence, it follows that $\beta_{i}\left(t_{i}^{b_{i}}, h\right)\left(\times_{j \neq i}\left(S_{j} \times T_{j}^{m . k-1}\right)^{r a t, m}\right)=1$. As such, we conclude that $t_{i}^{b_{i}}$ strongly believes $\times_{j \neq i}\left(S_{j} \times T_{j}^{m . k-1}\right)^{r a t . m}$.

Since $t_{i}^{b_{i}} \in T_{i}^{m . k-1}$ it follows that $t_{i}^{b_{i}} \in T_{i}^{m . k}$. We thus conclude that for every $b_{i} \in B_{i}^{m . k+1}$ we have that $t_{i}^{b_{i}} \in T_{i}^{m . k}$. Since, by (9.2), $t_{i}^{b_{i}}$ induces the conditional belief vector $b_{i}$, it follows that $b_{i} \in \hat{B}_{i}^{m . k}$. Hence, $B_{i}^{m . k+1} \subseteq \hat{B}_{i}^{m . k}$.
(iii) We show that $\hat{S}_{i}^{m \cdot k} \subseteq S_{i}^{m . k+1}$. Let $s_{i} \in \hat{S}_{i}^{m . k}$. Then, in particular, $s_{i} \in \hat{S}_{i}^{m \cdot k-1}$. By the induction assumption of (iii) it follows that $s_{i} \in S_{i}^{m . k}$. Since $s_{i} \in \hat{S}_{i}^{m . k}$, there is a $t_{i} \in T_{i}^{m . k}$ such that $s_{i}$ is optimal for $t_{i}$ from period $m$ onwards. Let $b_{i}$ be the conditional belief vector induced by $t_{i}$. As the expected utility depends only on first-order beliefs, $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards. Since $t_{i} \in T_{i}^{m . k}$ it follows, by definition, that $b_{i} \in \hat{B}_{i}^{m . k}$. By (i) it then follows that $b_{i} \in B_{i}^{m . k+1}$. Hence, $s_{i}$ is optimal for some $b_{i} \in B_{i}^{m . k+1}$ from period $m$ onwards. As we have seen above that $s_{i} \in S_{i}^{m \cdot k}$, we conclude that $s_{i} \in S_{i}^{m \cdot k+1}$. Hence, $\hat{S}_{i}^{m . k} \subseteq S_{i}^{m \cdot k+1}$.
(iv) We finally show that $S_{i}^{m \cdot k+1} \subseteq \hat{S}_{i}^{m . k}$. Let $s_{i} \in S_{i}^{m \cdot k+1}$. Then, by construction, $b_{i}\left[s_{i}\right] \in B_{i}^{m \cdot k+1}$ and $s_{i}$ is optimal for $b_{i}\left[s_{i}\right]$ from period $m$ onwards. By (ii) we know that $t_{i}^{b_{i}\left[s_{i}\right]} \in T_{i}^{m . k}$. Moreover, $t_{i}^{b_{i}\left[s_{i}\right]}$ induces the conditional belief vector $b_{i}\left[s_{i}\right]$. Since the expected utility depends only on first-order beliefs, we conclude that $s_{i}$ is optimal for $t_{i}^{b_{i}\left[s_{i}\right]}$ from period $m$ onwards. This implies that $\left(s_{i}, t_{i}^{b_{i}\left[s_{i}\right]}\right) \in\left(S_{i} \times T_{i}^{m . k}\right)^{r a t . m}$, and hence $s_{i} \in \hat{S}_{i}^{m . k}$. Thus, $S_{i}^{m . k+1} \subseteq \hat{S}_{i}^{m . k}$. This completes the proof of the claim. $\diamond$

We are now able to prove the theorem.
(a) Take first a strategy $s_{i}$ that is forward and backward rationalizable. Then, there is a conditional belief vector $b_{i} \in B_{i}^{L . K_{L}}$ such that $s_{i}$ is optimal for $b_{i}$ from the first period onwards. Note that $b_{i} \in B_{i}^{L . k+1}$ for all $k$ and hence, by part (ii) of the claim, $t_{i}^{b_{i}} \in T_{i}^{L . k}$ for all $k$. Therefore, $t_{i}^{b_{i}} \in T_{i}^{L}$, and hence $t_{i}^{b_{i}}$ expresses common backward strong belief in rationality. As $t_{i}^{b_{i}}$ induces the conditional belief vector $b_{i}$, and $s_{i}$ is optimal for $b_{i}$
from the first period onwards, it follows that $s_{i}$ is optimal for $t_{i}^{b_{i}}$ from the first period onwards. As such, $s_{i}$ is optimal, from the first period onwards, for a type that expresses common backward strong belief in rationality.

Conversely, suppose that $s_{i}$ is optimal, from the the first period onwards, for a type $t_{i}$ that expresses common backward strong belief in rationality. Hence, $t_{i} \in T_{i}^{L}$. Suppose that $t_{i}$ induces the conditional belief vector $b_{i}$. Then, $s_{i}$ is optimal, from the first period onwards, for $b_{i}$. Since $t_{i} \in T_{i}^{L . k}$ for all $k$, and $t_{i}$ induces the conditional belief vector $b_{i}$, it follows that $b_{i} \in \hat{B}_{i}^{L . k}$ for all $k$. By part (i) of the claim it follows that $b_{i} \in B_{i}^{L . k+1}$ for all $k$, and hence $b_{i}$ is forward and backward rationalizable. Since $s_{i}$ is optimal for $b_{i}$ from the first period onwards, we conclude that $s_{i}$ is forward and backward rationalizable.
(b) Take first a strategy $s_{i} \in S_{i}^{m .0}$. Then, $s_{i} \in S_{i}^{m+1 \cdot K_{m+1}}$. Hence, there is a conditional belief vector $b_{i} \in B_{i}^{m+1 . K_{m+1}}$ such that $s_{i}$ is optimal for $b_{i}$ from period $m+1$ onwards. Note that $b_{i} \in B_{i}^{m+1 . k+1}$ for all $k$ and hence, by part (ii) of the claim, $t_{i}^{b_{i}} \in T_{i}^{m+1 . k}$ for all $k$. Therefore, $t_{i}^{b_{i}} \in T_{i}^{m+1}$, and hence $t_{i}^{b_{i}}$ expresses common backward strong belief in rationality from period $m+1$ onwards. As $t_{i}^{b_{i}}$ induces the conditional belief vector $b_{i}$, and $s_{i}$ is optimal for $b_{i}$ from period $m+1$ onwards, it follows that $s_{i}$ is optimal for $t_{i}^{b_{i}}$ from period $m+1$ onwards. As such, $s_{i}$ is optimal, from period $m+1$ onwards, for a type that expresses common backward strong belief in rationality from period $m+1$ onwards.

Conversely, suppose that $s_{i}$ is optimal, from period $m+1$ onwards, for a type $t_{i}$ that expresses common backward strong belief in rationality from period $m+1$ onwards. Hence, $t_{i} \in T_{i}^{m+1}$. Suppose that $t_{i}$ induces the conditional belief vector $b_{i}$. Then, $s_{i}$ is optimal, from period $m+1$ onwards, for $b_{i}$. Since $t_{i} \in T_{i}^{m+1 . k}$ for all $k$, and $t_{i}$ induces the conditional belief vector $b_{i}$, it follows that $b_{i} \in \hat{B}_{i}^{m+1 . k}$ for all $k$. By part (i) of the claim it follows that $b_{i} \in B_{i}^{m+1 . k+1}$ for all $k$, and hence $b_{i} \in B_{i}^{m .0}$. Since $s_{i}$ is optimal for $b_{i}$ from period $m+1$ onwards, we conclude that $s_{i} \in S_{i}^{m .0}$.
(c) Take first a strategy $s_{i} \in S_{i}^{m \cdot k+1}$. Hence, there is a conditional belief vector $b_{i} \in B_{i}^{m \cdot k+1}$ such that $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards. By part (ii) of the claim we conclude that $t_{i}^{b_{i}} \in T_{i}^{m . k}$. As $t_{i}^{b_{i}}$ induces the conditional belief vector $b_{i}$, and $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards, it follows that $s_{i}$ is optimal for $t_{i}^{b_{i}}$ from period $m$ onwards. As such, $s_{i}$ is optimal, from period $m$ onwards, for a type in $T_{i}^{m . k}$ that expresses $k$-fold backward strong belief in rationality from period $m$ onwards.

Conversely, suppose that $s_{i}$ is optimal, from period $m$ onwards, for a type $t_{i} \in T_{i}^{m \cdot k}$ that expresses $k$-fold backward strong belief in rationality from period $m$ onwards. Suppose that $t_{i}$ induces the conditional belief vector $b_{i}$. Then, $s_{i}$ is optimal, from period $m$ onwards, for $b_{i}$. Since $t_{i} \in T_{i}^{m . k}$ and $t_{i}$ induces the conditional belief vector $b_{i}$, it follows that $b_{i} \in \hat{B}_{i}^{m . k}$. By part (i) of the claim it follows that $b_{i} \in B_{i}^{m . k+1}$. Since $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards, we conclude that $s_{i} \in S_{i}^{m . k+1}$.

This completes the proof.

### 9.3 Proof of Section 5

Proof of Theorem 5.1. Let $S_{i}^{f b r, m . k}$ and $B_{i}^{f b r, m . k}$ be the sets of strategies and conditional belief vectors for player $i$ that result from period $m$, round $k$, of the forward and backward rationalizability procedure. Similarly, we define the sets $S_{i}^{b r, m . k}$ and $B_{i}^{b r, m \cdot k}$ for the backwards rationalizability procedure. For every
period $m$, let $K_{m}$ be the first round where both procedures terminate at period $m$. We show, by induction on $m . k$, that for all players $i$,

$$
\begin{equation*}
B_{i}^{f b r, m \cdot k} \subseteq B_{i}^{b r, m \cdot k} \text { and } S_{i}^{f b r, m \cdot k} \subseteq S_{i}^{b r, m \cdot k} \tag{9.3}
\end{equation*}
$$

For $m . k=M .0$ this is true, since $B_{i}^{f b r, m \cdot k}=B_{i}^{b r, m \cdot k}=B_{i}$ and $S_{i}^{f b r, m \cdot k}=S_{i}^{b r, m \cdot k}=S_{i}$.
Now, take some $m . k \neq M .0$, and assume that (9.3) holds for $m+1 . K_{m+1}$ if $k=0$ or for $m . k-1$ if $k \geq 1$. If $k=0$ then, by definition, $B_{i}^{f b r, m .0}=B_{i}^{f b r, m+1 \cdot K_{m+1}}, B_{i}^{b r, m .0}=B_{i}^{b r, m+1 . K_{m+1}}, S_{i}^{f b r, m .0}=S_{i}^{f b r, m+1 . \overline{K_{m+1}}}$ and $S_{i}^{b r, m .0}=S_{i}^{b r, m+1 \cdot K_{m+1}}$. Thus, (9.3) would hold trivially, by the induction assumption.

Suppose now that $k \geq 1$ and that (9.3) holds for $m . k-1$. We first show that $B_{i}^{f b r, m . k} \subseteq B_{i}^{b r, m . k}$. Take some $b_{i} \in B_{i}^{f b r, m . k}$. Then, in particular, $b_{i} \in B_{i}^{f b r, m . k-1}$. By the induction assumption it follows that $b_{i} \in B_{i}^{b r, m . k-1}$. As $b_{i} \in B_{i}^{f b r, m . k}$, we know that $b_{i}$ strongly believes $S_{-i}^{f b r, m . k-1}$. Take some $h \in H_{i}^{m}$. Since so far no restrictions have been imposed on the optimality of strategies at information sets preceding $h$, strongly believing $S_{-i}^{f b r, m \cdot k-1}$ implies that $b_{i}(h)\left(S_{-i}^{f b r, m \cdot k-1}\right)=1$. As, by the induction assumption, $S_{-i}^{f b r, m \cdot k-1} \subseteq$ $S_{-i}^{b r, m \cdot k-1}$, it follows that $b_{i}(h)\left(S_{-i}^{b r, m \cdot k-1}\right)=1$. As $b_{i} \in B_{i}^{b r, m \cdot k-1}$, we conclude that $b_{i} \in B_{i}^{b r, m \cdot k}$. Hence, $B_{i}^{f b r, m \cdot k} \subseteq B_{i}^{b r, m \cdot k}$.

We next show that $S_{i}^{f b r, m . k} \subseteq S_{i}^{b r, m . k}$. Take some $s_{i} \in S_{i}^{f b r, m . k}$. Then, $s_{i}$ is optimal, from period $m$ onwards, for some $b_{i} \in B_{i}^{f b r, m . k}$. As we have seen above that $B_{i}^{f b r, m . k} \subseteq B_{i}^{b r, m . k}$, we conclude that $s_{i}$ is optimal, from period $m$ onwards, for some $b_{i} \in B_{i}^{b r, m . k}$. Hence, $s_{i} \in S_{i}^{b r, m . k}$. We have thus shown that $S_{i}^{f b r, m \cdot k} \subseteq S_{i}^{b r, m \cdot k}$.

By induction, it follows that $B_{i}^{f b r, L \cdot K_{L}} \subseteq B_{i}^{b r, L \cdot K_{L}}$ and $S_{i}^{f b r, L \cdot K_{L}} \subseteq S_{i}^{b r, L \cdot K_{L}}$, which completes the proof.

### 9.4 Proof of Section 6

Proof of Lemma 6.1. Without loss of generality, suppose that the first time period is 1. For every period $m \in\{1, \ldots, M\}$ and $k \in\left\{0,1,2, \ldots, K_{m}\right\}$, let $m$. $k$ be the elimination step in period $m$, round $k$, of the forward and backward rationalizability procedure. Here, $K_{m}$ denotes the last round of the procedure from period $m$ onwards. This leads to the sequence

$$
\left(D^{M .0}, D^{M .1}, \ldots, D^{M . K_{M}}, D^{M-1.0}, D^{M-1.1}, \ldots, D^{M-1 . K_{M-1}}, \ldots, D^{1.0}, D^{1.1}, \ldots, D^{1, K_{1}}\right)
$$

of products of strategy sets.
We show that this sequence is an elimination order for $s b$. By definition, $D^{M .0}=\times_{i \in I} S_{i}$ and $s b\left(D^{1 . K_{1}}\right)=$ $D^{1 . K_{1}}$. It remains to show condition (b) in the definition of an elimination order.

Consider first a step $m . k$ with $k \leq K_{m}-1$. Then, by definition, $D^{m \cdot k+1}=\times_{i \in I} D_{i}^{m \cdot k+1}$, where

$$
\begin{equation*}
D_{i}^{m . k+1}=\left\{s_{i} \in D_{i}^{m . k} \mid \text { there is some } b_{i} \in B_{i} \text { that strongly believes } D_{-i}^{M_{i} .0}, D_{-i}^{M_{.1}}, \ldots, D_{-i}^{m . k}\right. \tag{9.4}
\end{equation*}
$$ such that $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards \}

for every player $i$. Define, for every player $i$, the set

$$
\begin{gather*}
E_{i}^{m . k+1}=\left\{s_{i} \in D_{i}^{m \cdot k} \mid \text { there is some } b_{i} \in B_{i} \text { that strongly believes } D_{-i}^{m . k}\right. \\
\text { such that } s_{i} \text { is optimal for } b_{i} \text { at every } h \in H\left(D^{m \cdot k}\right) \cap H_{i}\left(s_{i}\right) \\
\text { that belongs to } \left.H^{\tau} \text { for some } \tau \geq m\right\} . \tag{9.5}
\end{gather*}
$$

Claim. $E_{i}^{m \cdot k+1}=D_{i}^{m \cdot k+1}$.
Proof of claim. Clearly, $D_{i}^{m \cdot k+1} \subseteq E_{i}^{m \cdot k+1}$. To prove that $E_{i}^{m \cdot k+1} \subseteq D_{i}^{m . k+1}$, take some $s_{i} \in E_{i}^{m \cdot k+1}$. We will show that $s_{i} \in D_{i}^{m . k+1}$. As $s_{i} \in E_{i}^{m . k+1}$, there is some $b_{i}^{m . k} \in B_{i}$ that strongly believes $D_{-i}^{m . k}$ such that $s_{i}$ is optimal for $b_{i}^{m . k}$ at every $h \in H\left(D^{m . k}\right) \cap H_{i}\left(s_{i}\right)$ that belongs to $H^{\tau}$ for some $\tau \geq m$. To show that $s_{i} \in D_{i}^{m \cdot k+1}$ we distinguish two cases: (1) $k \geq 1$ and (2) $k=0$.
Case 1. Suppose that $k \geq 1$. As $s_{i} \in E_{i}^{m \cdot k+1}$ we know, by definition, that $s_{i} \in D_{i}^{m . k}$. Hence, there is some $b_{i}^{\prime} \in B_{i}$ that strongly believes $D_{-i}^{M_{i} 0}, \ldots, D_{-i}^{m . k-1}$ such that $s_{i}$ is optimal for $b_{i}^{\prime}$ from period $m$ onwards. Define the conditional belief vector $b_{i}$ where

$$
b_{i}(h):=\left\{\begin{aligned}
b_{i}^{m \cdot k}(h), & \text { if } D_{-i}^{m \cdot k} \cap S_{-i}(h) \neq \emptyset \\
b_{i}^{\prime}(h), & \text { otherwise }
\end{aligned}\right.
$$

for every $h \in H_{i}$.
Then, by construction, $b_{i}$ strongly believes $D_{-i}^{M_{i} 0}, D_{-i}^{M_{i},}, \ldots, D_{-i}^{m_{i} k}$. To show that $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards, take some $h \in H_{i}\left(s_{i}\right) \cap H^{\tau}$ for some $\tau \geq m$. We distinguish two cases.

If $D_{-i}^{m_{\cdot} k} \cap S_{-i}(h) \neq \emptyset$, then $h \in H\left(D^{m \cdot k}\right) \cap H_{i}\left(s_{i}\right)$ since $s_{i} \in D_{i}^{m \cdot k}$. Moreover, $b_{i}(h)=b_{i}^{m \cdot k}(h)$. As, by construction, $s_{i}$ is optimal for $b_{i}^{m . k}$ at $h$, it follows that $s_{i}$ is optimal for $b_{i}$ at $h$.

If $D_{-i}^{m \cdot k} \cap S_{-i}(h)=\emptyset$ then, by construction, $b_{i}(h)=b_{i}^{\prime}(h)$. As $s_{i}$ is optimal for $b_{i}^{\prime}$ at $h$, it follows that $s_{i}$ is optimal for $b_{i}$ at $h$. Hence, $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards.

We finally show that $b_{i}$ is in $B_{i}$, by proving that it satisfies Bayesian updating. Consider some information sets $h, h^{\prime} \in H_{i}$, where $h$ precedes $h^{\prime}$. We distinguish three cases:
(i) If $D_{-i}^{m . k} \cap S_{-i}(h) \neq \emptyset$ and $D_{-i}^{m \cdot k} \cap S_{-i}\left(h^{\prime}\right) \neq \emptyset$, then $b_{i}$ coincides with $b_{i}^{m . k} \in B_{i}$ at $h$ and $h^{\prime}$. Since $b_{i}^{m . k}$ satisfies Bayesian updating, it follows that $b_{i}$ satisfies Bayesian updating if the game moves from $h$ to $h^{\prime}$.
(ii) If $D_{-i}^{m \cdot k} \cap S_{-i}(h)=\emptyset$ and $D_{-i}^{m \cdot k} \cap S_{-i}\left(h^{\prime}\right)=\emptyset$, then $b_{i}$ coincides with $b_{i}^{\prime} \in B_{i}$ at $h$ and $h^{\prime}$. Since $b_{i}^{\prime}$ satisfies Bayesian updating, it follows that $b_{i}$ satisfies Bayesian updating if the game moves from $h$ to $h^{\prime}$.
(iii) Suppose, finally, that $D_{-i}^{m \cdot k} \cap S_{-i}(h) \neq \emptyset$ and $D_{-i}^{m \cdot k} \cap S_{-i}\left(h^{\prime}\right)=\emptyset$. Then, $b_{i}(h)=b_{i}^{m . k}(h)$ and $b_{i}\left(h^{\prime}\right)=b_{i}^{\prime}\left(h^{\prime}\right)$. As $D_{-i}^{m . k} \cap S_{-i}\left(h^{\prime}\right)=\emptyset$ and $b_{i}^{m . k}$ strongly believes $D_{-i}^{m . k}$, we have that $b_{i}^{m . k}(h)\left(D_{-i}^{m . k}\right)=1$. Since $D_{-i}^{m \cdot k} \cap S_{-i}\left(h^{\prime}\right)=\emptyset$, it thus follows that $b_{i}^{m . k}(h)\left(S_{-i}\left(h^{\prime}\right)\right)=0$. Thus, $b_{i}$ trivially satisfies Bayesian updating if the game moves from $h$ to $h^{\prime}$.

By combining the cases (i), (ii) and (iii), we see that $b_{i}$ satisfies Bayesian updating.
Hence, for the strategy $s_{i} \in E_{i}^{m . k+1}$ there is some $b_{i} \in B_{i}$ that strongly believes $D_{-i}^{M_{i} .0}, D_{-i}^{M .1}, \ldots, D_{-i}^{m . k}$ such that $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards. That is, $s_{i} \in D_{i}^{m . k+1}$, which completes Case 1 .

Case 2. Suppose that $k=0$. If $m=M$, then $D^{m . k}=D^{M .0}=\times_{j \in I} S_{j}$. In that case, it would follow immediately that $s_{i} \in D_{i}^{m . k+1}=D_{i}^{M .1}$.

Suppose now that $k=0$ and $m \leq M-1$. Then, $D^{m . k}=D^{m .0}=D^{m+1 . K_{m+1}}$. Since $s_{i} \in D_{i}^{m .0}=$ $D^{m+1 . K_{m+1}}$, there is some $b_{i}^{\prime} \in B_{i}$ that strongly believes $D_{-i}^{M .0}, \ldots, D_{-i}^{m+1 . K_{m+1}-1}$ such that $s_{i}$ is optimal for $b_{i}^{\prime}$ from period $m+1$ onwards. Define the conditional belief vector $b_{i}$ where

$$
b_{i}(h):=\left\{\begin{array}{cl}
b_{i}^{m .0}(h), & \text { if } D_{-i}^{m .0} \cap S_{-i}(h) \neq \emptyset \\
b_{i}^{\prime}(h), & \text { otherwise }
\end{array}\right.
$$

for every $h \in H_{i}$.
To show that $s_{i} \in D_{i}^{m . k+1}=D_{i}^{m .1}$, we show that $b_{i} \in B_{i}$, that $b_{i}$ strongly believes $D_{-i}^{M .0}, \ldots, D_{-i}^{m+1 . K_{m+1}-1}, D_{-i}^{m_{i} 0}$, and that $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards.

Note that, by construction, $b_{i}$ strongly believes $D_{-i}^{M .0}, \ldots, D_{-i}^{m+1 . K_{m+1}-1}$ and strongly believes $D_{-i}^{m .0}$. In the same way as for Case 1, it can be shown that $b_{i}$ satisfies Bayesian updating, and hence $b_{i} \in B_{i}$.

We finally show that $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards. Take some information set $h \in$ $H_{i}\left(s_{i}\right) \cap H^{\tau}$, for some $\tau \geq m$.

If $D_{-i}^{m .0} \cap S_{-i}(h) \neq \emptyset$, then $h \in H\left(D^{m .0}\right) \cap H_{i}\left(s_{i}\right)$ since $s_{i} \in D_{i}^{m .0}$. Thus, by construction, $s_{i}$ is optimal for $b_{i}^{m .0}$ at $h$. Since $b_{i}^{m .0}(h)=b_{i}(h)$, we know that $s_{i}$ is optimal for $b_{i}$ at $h$.

If $D_{-i}^{m_{0} 0} \cap S_{-i}(h)=\emptyset$, then, by definition, $b_{i}(h)=b_{i}^{\prime}(h)$. Since $D_{-i}^{m_{i} 0} \cap S_{-i}(h)=\emptyset$, it must necessarily be that $h \in H^{\tau}$ with $\tau \geq m+1$. Indeed, since $D_{-i}^{m .0}$ only imposes restrictions on actions at period $m+1$ and later, it follows that $D_{-i}^{m .0} \cap S_{-i}(h) \neq \emptyset$ for every $h \in H_{i} \cap H^{m}$. As $s_{i}$ is optimal for $b_{i}^{\prime}$ from period $m+1$ onwards, we conclude that $s_{i}$ is optimal for $b_{i}^{\prime}(h)$ at $h$, and thus also for $b_{i}(h)$ at $h$.

Hence, $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards. Altogether, we see that $b_{i} \in B_{i}$, that $b_{i}$ strongly believes $D_{-i}^{M .0}, \ldots, D_{-i}^{m+1 . K_{m+1}-1}, D_{-i}^{m .0}$, and that $s_{i}$ is optimal for $b_{i}$ from period $m$ onwards. Hence, $s_{i} \in$ $D_{i}^{m .1}=D_{i}^{m . k+1}$, which completes Case 2.

By Cases 1 and 2 we thus conclude that $E_{i}^{m \cdot k+1} \subseteq D_{i}^{m \cdot k+1}$, and hence $E_{i}^{m \cdot k+1}=D_{i}^{m \cdot k+1}$. This completes the proof of the claim. $\diamond$

Since, by construction, $s b\left(D^{m . k}\right) \subseteq E^{m . k+1}$, it follows by the claim that

$$
\begin{equation*}
s b\left(D^{m \cdot k}\right) \subseteq E^{m \cdot k+1}=D^{m \cdot k+1} \subseteq D^{m \cdot k} \tag{9.6}
\end{equation*}
$$

Consider now the case where $k=K_{m}$. Then the next step is $m-1.0$ where, by definition, $D^{m-1.0}=$ $D^{m \cdot K_{m}}$. Hence, we trivially have that

$$
\begin{equation*}
s b\left(D^{m \cdot K_{m}}\right) \subseteq D^{m-1.0} \subseteq D^{m \cdot K_{m}} \tag{9.7}
\end{equation*}
$$

By (9.6) and (9.7) we conclude that ( $D^{M .0}, \ldots, D^{1 . K_{1}}$ ) is an elimination order for $s b$. This completes the proof.

### 9.5 Proofs of Section 8

Proof of Theorem 8.1. Let $h^{*}$ be the information set that coincides with the initial history of $\Gamma$. Then, every strategy $\hat{s}_{i} \in S_{i}^{\hat{\Gamma}}\left(h^{*}\right)$ in the supergame that allows for $h^{*}$ to be reached naturally induces a strategy $f_{i}\left(\hat{s}_{i}\right) \in S_{i}^{\Gamma}$ in the subgame, such that $\hat{s}_{i}$ and $f_{i}\left(\hat{s}_{i}\right)$ prescribe the same actions at all information sets in $H_{i}^{\hat{\Gamma}}\left(\hat{s}_{i}\right) \cap H_{i}^{\Gamma}$. Note that the mapping $f_{i}$ is onto.

Now, consider a conditional belief vector $\hat{b}_{i}$ for player $i$ in the supergame $\hat{\Gamma}$. Then, $\hat{b}_{i}$ naturally induces the conditional belief vector $g_{i}\left(\hat{b}_{i}\right)$ in the subgame $\Gamma$, where for every information set $h \in H_{i}^{\Gamma}$ and every opponents' strategy combination $\left(s_{j}\right)_{j \neq i} \in S_{-i}(h)$,

$$
\begin{equation*}
\left(g_{i}\left(\hat{b}_{i}\right)\right)(h)\left(\left(s_{j}\right)_{j \neq i}\right):=\sum_{\left(\hat{s}_{j}\right)_{j \neq i} \in S_{-i}^{\hat{1}}(h): f_{j}\left(\hat{s}_{j}\right)=s_{j} \text { for all }} \hat{b}_{j \neq i}(h)\left(\left(\hat{s}_{j}\right)_{j \neq i}\right) . \tag{9.8}
\end{equation*}
$$

It may easily be verified that $g_{i}\left(\hat{b}_{i}\right)$ satisfies Bayesian updating whenever possible and that the mapping $g_{i}: B_{i}^{\hat{\Gamma}} \rightarrow B_{i}^{\Gamma}$ is onto.

Suppose, without loss of generality, that the supergame $\hat{\Gamma}$ starts at period 1 , that the subgame $\Gamma$ starts at the singleton information set $h^{*}$ in period $L \geq 1$, and that the last period in which players are active is $M$ in both $\hat{\Gamma}$ and $\Gamma$. It is of course possible that some terminal histories in $\hat{\Gamma}$ are longer than in $\Gamma$, but every terminal history in $\hat{\Gamma}$ that passes through information sets in $\Gamma$ will be in $\Gamma$ as well. This will therefore not affect $Z\left(S^{f b r}(\Gamma \mid \hat{\Gamma})\right)$.

For every player $i$, period $m \in\{1, \ldots, M\}$ and round $k$, let $\hat{B}_{i}^{m . k}$ and $\hat{S}_{i}^{m . k}$ be the set of conditional belief vectors and the set of strategies for player $i$ that survive round $k$ at period $m$ in the backward and forward rationalizability procedure for $\hat{\Gamma}$. Similarly, we denote by $B_{i}^{m . k}$ and $S_{i}^{m . k}$ the set of conditional belief vectors and the set of strategies for player $i$ that survive round $k$ at period $m$ in the backward and forward rationalizability procedure for $\Gamma$. For every period $m \in\{L, \ldots, M\}$, let $K_{m}$ be the earliest round in this period at which both procedures terminate.

Claim. For every player $i$, period $m \in\{L, \ldots, M\}$ and round $k \in\left\{1, \ldots, K_{m}\right\}$, we have that

$$
g_{i}\left(\hat{B}_{i}^{m \cdot k}\right)=B_{i}^{m \cdot k} \text { and } f_{i}\left(\hat{S}_{i}^{m \cdot k}\right)=S_{i}^{m \cdot k} .
$$

Proof of claim. By induction on m.k. We start by with m.k $=$ M.0. Then, $\hat{B}_{i}^{M .0}=B_{i}^{\hat{\Gamma}}, B_{i}^{M .0}=B_{i}^{\Gamma}$, $\hat{S}_{i}^{M .0}=S_{i}^{\hat{\Gamma}}$ and $S_{i}^{M .0}=S_{i}^{\Gamma}$, which implies that

$$
g_{i}\left(\hat{B}_{i}^{M .0}\right)=g_{i}\left(B_{i}^{\hat{\Gamma}}\right)=B_{i}^{\Gamma}=B_{i}^{M .0} \text { and } f_{i}\left(\hat{S}_{i}^{M .0}\right)=f_{i}\left(S_{i}^{\hat{\Gamma}}\right)=S_{i}^{\Gamma}=S_{i}^{M .0}
$$

since both $g_{i}$ and $f_{i}$ are onto.
Now, take some $m . k \neq M .0$, and assume that the claim holds for $m+1 . K_{m+1}$ if $k=0$ or for $m . k-1$ if $k \geq 1$. If $k=0$ then, by definition, $\hat{B}_{i}^{m .0}=\hat{B}_{i}^{m+1 \cdot K_{m+1}}, B_{i}^{m .0}=B_{i}^{m+1 \cdot K_{m+1}}, \hat{S}_{i}^{m .0}=\hat{S}_{i}^{m+1 \cdot K_{m+1}}$ and $S_{i}^{m .0}=S_{i}^{m+1 . K_{m+1}}$. Thus, the claim would hold by the induction assumption.

Assume now that $k \geq 1$ and that the claim holds for $m . k-1$. To show that $g_{i}\left(\hat{B}_{i}^{m . k}\right) \subseteq B_{i}^{m . k}$, take some $b_{i} \in g_{i}\left(\hat{B}_{i}^{m . k}\right)$. Then, by definition, there is some $\hat{b}_{i} \in \hat{B}_{i}^{m . k}$ such that $b_{i}=g_{i}\left(\hat{b}_{i}\right)$. By definition of $\hat{B}_{i}^{m . k}$, it must be that $\hat{b}_{i}$ strongly believes $\hat{S}_{-i}^{m \cdot k-1}$. In particular, for every $h \in H_{i}^{\Gamma}$ it must be that

$$
\begin{equation*}
\hat{b}_{i}(h)\left(\hat{S}_{-i}^{m \cdot k-1}\right)=1 \text { whenever } \hat{S}_{-i}^{m \cdot k-1} \cap S_{-i}(h) \neq \emptyset . \tag{9.9}
\end{equation*}
$$

Take such $h \in H_{i}^{\Gamma}$. We will show that

$$
\begin{equation*}
\left(g_{i}\left(\hat{b}_{i}\right)\right)(h)\left(S_{-i}^{m \cdot k-1}\right)=1 \text { whenever } S_{-i}^{m \cdot k-1} \cap S_{-i}^{\Gamma}(h) \neq \emptyset . \tag{9.10}
\end{equation*}
$$

Suppose that $S_{-i}^{m \cdot k-1} \cap S_{-i}^{\Gamma}(h) \neq \emptyset$. By the induction assumption we know that $S_{-i}^{m . k-1}=f_{-i}\left(\hat{S}_{-i}^{m . k-1}\right)$, where $f_{-i}\left(\hat{S}_{-i}^{m . k-1}\right):=\times_{j \neq i} f_{j}\left(\hat{S}_{j}^{m . k-1}\right)$. Moreover, by construction, the sets $\hat{S}_{-i}^{m . k-1}$ and $f_{-i}\left(\hat{S}_{-i}^{m . k-1}\right)$ induce the same actions in $\Gamma$. Since $m \geq L$, it follows that $\hat{S}_{-i}^{m . k-1} \cap S_{-i}^{\hat{\Gamma}}(h) \neq \emptyset$. By (9.9) we then conclude that $\hat{b}_{i}(h)\left(\hat{S}_{-i}^{m \cdot k-1}\right)=1$. It then follows by (9.8) that

$$
\left(g_{i}\left(\hat{b}_{i}\right)\right)(h)\left(f_{-i}\left(\hat{S}_{-i}^{m \cdot k-1}\right)\right)=1 .
$$

Since, by the induction assumption, $S_{-i}^{m \cdot k-1}=f_{-i}\left(\hat{S}_{-i}^{m \cdot k-1}\right)$, we conclude that

$$
\left(g_{i}\left(\hat{b}_{i}\right)\right)(h)\left(S_{-i}^{m \cdot k-1}\right)=1,
$$

which establishes (9.10).
As this holds for every $h \in H_{i}^{\Gamma}$ with $S_{-i}^{m . k-1} \cap S_{-i}^{\Gamma}(h) \neq \emptyset$, it follows that $g_{i}\left(\hat{b}_{i}\right)$ strongly believes $S_{-i}^{m . k-1}$. Moreover, as $\hat{b}_{i} \in \hat{B}_{i}^{m . k-1}$ and, by the induction assumption, $g_{i}\left(\hat{B}_{i}^{m . k-1}\right)=B_{i}^{m . k-1}$, we conclude that $g_{i}\left(\hat{b}_{i}\right) \in B_{i}^{m \cdot k-1}$. Hence, by definition, $b_{i}=g_{i}\left(\hat{b}_{i}\right) \in B_{i}^{m . k}$. Since this applies to every $b_{i} \in g_{i}\left(\hat{B}_{i}^{m \cdot k}\right)$, it follows that $g_{i}\left(\hat{B}_{i}^{m \cdot k}\right) \subseteq B_{i}^{m . k}$.

To show that $B_{i}^{m . k} \subseteq g_{i}\left(\hat{B}_{i}^{m . k}\right)$, take some $b_{i} \in B_{i}^{m . k}$. Then, in particular, $b_{i} \in B_{i}^{m \cdot k-1}$. As, by the induction assumption, $B_{i}^{m \cdot k-1}=g_{i}\left(\hat{B}_{i}^{m . k-1}\right)$, there is some $\hat{b}_{i} \in \hat{B}_{i}^{m . k-1}$ such that $b_{i}=g_{i}\left(\hat{b}_{i}\right)$.

Moreover, as $b_{i} \in B_{i}^{m . k}$ we know, by definition, that $b_{i}$ strongly believes $S_{-i}^{m . k-1}$. Hence, for every $h \in H_{i}^{\Gamma}$ we have that

$$
b_{i}(h)\left(S_{-i}^{m . k-1}\right)=1 \text { whenever } S_{-i}^{m . k-1} \cap S_{-i}^{\Gamma}(h) \neq \emptyset .
$$

As, by the induction assumption, $S_{-i}^{m \cdot k-1}=f_{-i}\left(\hat{S}_{-i}^{m \cdot k-1}\right)$, it follows that

$$
\begin{equation*}
b_{i}(h)\left(f_{-i}\left(\hat{S}_{-i}^{m \cdot k-1}\right)\right)=1 \text { whenever } f_{-i}\left(\hat{S}_{-i}^{m . k-1}\right) \cap S_{-i}^{\Gamma}(h) \neq \emptyset . \tag{9.11}
\end{equation*}
$$

By construction, $f_{-i}\left(\hat{S}_{-i}^{m . k-1}\right)$ prescribes the same actions in the subgame $\Gamma$ as $\hat{S}_{-i}^{m . k-1}$. Moreover, as $m \geq L$ and the first history of $\Gamma$ is in period $L$, the set $\hat{S}_{-i}^{m \cdot k-1}$ imposes no restrictions on actions before $\Gamma$ starts. We therefore have that

$$
\begin{equation*}
f_{-i}\left(\hat{S}_{-i}^{m . k-1}\right) \cap S_{-i}^{\Gamma}(h) \neq \emptyset \text { if and only if } \hat{S}_{-i}^{m . k-1} \cap S_{-i}^{\Gamma}(h) \neq \emptyset . \tag{9.12}
\end{equation*}
$$

By combining (9.11) and (9.12), we see that for every $h \in H_{i}^{\Gamma}$,

$$
\begin{equation*}
b_{i}(h)\left(f_{-i}\left(\hat{S}_{-i}^{m \cdot k-1}\right)\right)=1 \text { whenever } \hat{S}_{-i}^{m \cdot k-1} \cap S_{-i}^{\Gamma}(h) \neq \emptyset . \tag{9.13}
\end{equation*}
$$

Since $b_{i}=g_{i}\left(\hat{b}_{i}\right)$ for some $\hat{b}_{i} \in \hat{B}_{i}^{m . k-1}$, it follows by (9.13) and (9.8) that we can choose $\hat{b}_{i} \in \hat{B}_{i}^{m \cdot k-1}$ such that

$$
\text { for every } h \in H_{i}^{\hat{\Gamma}} \text {, we have } \hat{b}_{i}(h)\left(\hat{S}_{-i}^{m \cdot k-1}\right)=1 \text { whenever } \hat{S}_{-i}^{m . k-1} \cap S_{-i}^{\Gamma}(h) \neq \emptyset .
$$

This means that $\hat{b}_{i}$ strongly believes $\hat{S}_{-i}^{m . k-1}$. As $\hat{b}_{i} \in \hat{B}_{i}^{m . k-1}$, it follows that $\hat{b}_{i} \in \hat{B}_{i}^{m . k}$. Since $g_{i}\left(\hat{b}_{i}\right)=b_{i}$ we conclude that $b_{i} \in g_{i}\left(\hat{B}_{i}^{m . k}\right)$. As this holds for every $b_{i} \in B_{i}^{m . k}$ we conclude that $B_{i}^{m . k} \subseteq g_{i}\left(\hat{B}_{i}^{m . k}\right)$. Together with our insight above that $g_{i}\left(\hat{B}_{i}^{m . k}\right) \subseteq B_{i}^{m . k}$, it follows that $g_{i}\left(\hat{B}_{i}^{m . k}\right)=B_{i}^{m . k}$.

We next show that $f_{i}\left(\widehat{S}_{i}^{m . k}\right)=S_{i}^{m . k}$ for every player $i$. To prove that $f_{i}\left(\hat{S}_{i}^{m . k}\right) \subseteq S_{i}^{m . k}$, take some $s_{i} \in f_{i}\left(\hat{S}_{i}^{m . k}\right)$. Then, there is some $\hat{s}_{i} \in \hat{S}_{i}^{m . k}$ such that $s_{i}=f_{i}\left(\hat{s}_{i}\right)$. By definition of $\overline{\hat{S}}_{i}^{m . k}$, there is some $\hat{b}_{i} \in \hat{B}_{i}^{m . k}$ such that $\hat{s}_{i}$ is optimal for $\hat{b}_{i}$ at every $h \in H_{i}^{\hat{\Gamma}}\left(\hat{s}_{i}\right)$ from period $m$ onwards.

Take some $h \in H_{i}^{\Gamma}\left(s_{i}\right)$ from period $m$ onwards. We will show that $s_{i}$ is optimal for $\left(g_{i}\left(\hat{b}_{i}\right)\right)(h)$ at $h$. Recall that, for every $\hat{s}_{i}^{\prime} \in \hat{S}_{i}$, the transformed strategy $f_{i}\left(\hat{s}_{i}^{\prime}\right)$ induces the same actions as $\hat{s}_{i}$ at information sets in $\Gamma$. This insight, together with (9.8), leads to the conclusion that

$$
\begin{equation*}
u_{i}\left(\hat{s}_{i}^{\prime}, \hat{b}_{i}(h)\right)=u_{i}\left(f_{i}\left(\hat{s}_{i}^{\prime}\right),\left(g_{i}\left(\hat{b}_{i}\right)\right)(h) \text { for all } \hat{s}_{i}^{\prime} \in S_{i}^{\hat{\Gamma}}(h)\right. \tag{9.14}
\end{equation*}
$$

As $\hat{s}_{i}$ is optimal for $\hat{b}_{i}$ at $h$, we know that

$$
u_{i}\left(\hat{s}_{i}, \hat{b}_{i}(h)\right) \geq u_{i}\left(\hat{s}_{i}^{\prime}, \hat{b}_{i}(h)\right) \text { for all } \hat{s}_{i}^{\prime} \in S_{i}^{\hat{\Gamma}}(h)
$$

Together with (9.14), this yields

$$
u_{i}\left(f_{i}\left(\hat{s}_{i}\right),\left(g_{i}\left(\hat{b}_{i}\right)\right)(h) \geq u_{i}\left(f_{i}\left(\hat{s}_{i}^{\prime}\right),\left(g_{i}\left(\hat{b}_{i}\right)\right)(h) \text { for all } \hat{s}_{i}^{\prime} \in S_{i}^{\hat{\Gamma}}(h) .\right.\right.
$$

As $s_{i}=f_{i}\left(\hat{s}_{i}\right)$ and $f_{i}\left(S_{i}^{\hat{\Gamma}}(h)\right)=S_{i}^{\Gamma}(h)$, it follows that

$$
u_{i}\left(s_{i},\left(g_{i}\left(\hat{b}_{i}\right)\right)(h) \geq u_{i}\left(s_{i}^{\prime},\left(g_{i}\left(\hat{b}_{i}\right)\right)(h) \text { for all } s_{i}^{\prime} \in S_{i}^{\Gamma}(h)\right.\right.
$$

Since this holds for every $h \in H_{i}^{\Gamma}\left(s_{i}\right)$ from period $m$ onwards, we conclude that $s_{i}$ is optimal for $g_{i}\left(\hat{b}_{i}\right)$ at all $h \in H_{i}^{\Gamma}\left(s_{i}\right)$ from period $m$ onwards.

As $\hat{b}_{i} \in \hat{B}_{i}^{m . k}$, we know from above that $g_{i}\left(\hat{b}_{i}\right) \in B_{i}^{m . k}$. Since $s_{i}$ is optimal for $g_{i}\left(\hat{b}_{i}\right)$ at all $h \in H_{i}^{\Gamma}\left(s_{i}\right)$ from period $m$ onwards, it follows, by definition, that $s_{i}=f_{i}\left(\hat{s}_{i}\right) \in S_{i}^{m . k}$. As this holds for every $s_{i} \in f_{i}\left(\hat{S}_{i}^{m . k}\right)$, we conclude that $f_{i}\left(\hat{S}_{i}^{m . k}\right) \subseteq S_{i}^{m . k}$.

We next prove that $S_{i}^{m . \bar{k}} \subseteq f_{i}\left(\hat{S}_{i}^{m . k}\right)$. Take some $s_{i} \in S_{i}^{m . k}$. Then, by definition, there is some $b_{i} \in B_{i}^{m . k}$ such that $s_{i}$ is optimal for $b_{i}$ at every $h \in H_{i}^{\Gamma}\left(s_{i}\right)$ from period $m$ onwards.

From above we know that $B_{i}^{m . k}=g_{i}\left(\hat{B}_{i}^{m . k}\right)$, and hence there is some $\hat{b}_{i} \in \hat{B}_{i}^{m . k}$ with $b_{i}=g_{i}\left(\hat{b}_{i}\right)$. Choose some strategy $\hat{s}_{i} \in S_{i}^{\hat{\Gamma}}$ such that (i) $f_{i}\left(\hat{s}_{i}\right)=s_{i}$, and (ii) $\hat{s}_{i}$ is optimal for $\hat{b}_{i}$ at every $h \in H_{i}^{\hat{\Gamma}}\left(\hat{s}_{i}\right) \backslash H_{i}^{\Gamma}$ from period $m$ onwards.

Now, take some $h \in H_{i}^{\Gamma}\left(s_{i}\right)$ from period $m$ onwards. As $s_{i}$ is optimal for $b_{i}$ at $h$, we have that

$$
u_{i}\left(s_{i}, b_{i}(h)\right) \geq u_{i}\left(s_{i}^{\prime}, b_{i}(h)\right) \text { for all } s_{i}^{\prime} \in S_{i}^{\Gamma}(h) .
$$

Since $s_{i}=f_{i}\left(\hat{s}_{i}\right)$ and $b_{i}=g_{i}\left(\hat{b}_{i}\right)$, we know that

$$
u_{i}\left(f_{i}\left(\hat{s}_{i}\right),\left(g_{i}\left(\hat{b}_{i}\right)\right)(h)\right) \geq u_{i}\left(f_{i}\left(\hat{s}_{i}^{\prime}\right),\left(g_{i}\left(\hat{b}_{i}\right)\right)(h)\right) \text { for all } \hat{s}_{i}^{\prime} \in S_{i}^{\hat{\Gamma}}(h)
$$

Together with (9.14) we then conclude that

$$
u_{i}\left(\hat{s}_{i}, \hat{b}_{i}(h)\right) \geq u_{i}\left(\hat{s}_{i}^{\prime}, \hat{b}_{i}(h)\right) \text { for all } \hat{s}_{i}^{\prime} \in S_{i}^{\hat{\Gamma}}(h)
$$

which means that $\hat{s}_{i}$ is optimal for $\hat{b}_{i}$ at $h$. As this holds for every $h \in H_{i}^{\Gamma}\left(\hat{s}_{i}\right)$ from period $m$ onwards, and since we know from above that $\hat{s}_{i}$ is optimal for $\hat{b}_{i}$ at every $h \in H_{i}^{\hat{\Gamma}}\left(\hat{s}_{i}\right) \backslash H_{i}^{\Gamma}$ from period $m$ onwards, we conclude that $\hat{s}_{i}$ is optimal for $\hat{b}_{i}$ at every $h \in H_{i}^{\hat{\Gamma}}\left(\hat{s}_{i}\right)$ from period $m$ onwards. This, together with the fact that $\hat{b}_{i} \in \hat{B}_{i}^{m . k}$, implies that $\hat{s}_{i} \in \hat{S}_{i}^{m . k}$.

As $s_{i}=f_{i}\left(\hat{s}_{i}\right)$, we conclude that $s_{i} \in f_{i}\left(\hat{S}_{i}^{m . k}\right)$. Since this holds for every $s_{i} \in S_{i}^{m . k}$, we conclude that $S_{i}^{m . k} \subseteq f_{i}\left(\hat{S}_{i}^{m \cdot k}\right)$. Together with the insight above that $f_{i}\left(\hat{S}_{i}^{m . k}\right) \subseteq S_{i}^{m . k}$, it follows that $f_{i}\left(\hat{S}_{i}^{m . k}\right)=S_{i}^{m . k}$.

By induction on $m . k$, the proof of the claim is complete. $\diamond$
To prove supergame monotonicity, take some $s_{i} \in S_{i}^{f b r}(\Gamma \mid \hat{\Gamma})$. Then, there is some conditional belief vector $\hat{b}_{i} \in \hat{B}_{i}^{1 . K_{1}}$ that survives the forward and backward rationalizability procedure in $\hat{\Gamma}$ such that $s_{i}$ is optimal for $\hat{b}_{i}$ at all $h \in H_{i}^{\Gamma}\left(s_{i}\right)$. In particular, we then know that $\hat{b}_{i} \in \hat{B}_{i}^{L . K_{L}}$, where $L$ is the period where the subgame $\Gamma$ starts. By the claim it follows that $g_{i}\left(\hat{b}_{i}\right) \in B_{i}^{L . K_{L}}$, which means that $g_{i}\left(\hat{b}_{i}\right) \in B_{i}^{f b r}(\Gamma)$.

Since $s_{i}$ is optimal for $\hat{b}_{i}$ at all $h \in H_{i}^{\Gamma}\left(s_{i}\right)$ it follows by (9.14) that $s_{i}$ is optimal for $g_{i}\left(\hat{b}_{i}\right)$ at all $h \in H_{i}^{\Gamma}\left(s_{i}\right)$. Since $g_{i}\left(\hat{b}_{i}\right) \in B_{i}^{f b r}(\Gamma)$ we conclude that $s_{i} \in S_{i}^{f b r}(\Gamma \mid \Gamma)$. As this holds for every $s_{i} \in S_{i}^{f b r}(\Gamma \mid$ $\hat{\Gamma}$ ), we conclude that $S_{i}^{f b r}(\Gamma \mid \hat{\Gamma}) \subseteq S_{i}^{f b r}(\Gamma \mid \Gamma)$, and hence supergame monotonicity holds for the forward and backward rationalizability procedure. This completes the proof.

Proof of Corollary 8.1. Let $z \in Z\left(S^{f b r}(\Gamma \mid \hat{\Gamma})\right)$. Then, there is some $\left(s_{i}\right)_{i \in I} \in \times_{i \in I} S_{i}^{f b r}(\Gamma \mid \hat{\Gamma})$ such that $z$ is induced by $\left(s_{i}\right)_{i \in I}$. By Theorem 8.1 we know that $\left(s_{i}\right)_{i \in I} \in \times_{i \in I} S_{i}^{f b r}(\Gamma \mid \Gamma)$, and hence $z \in Z\left(S^{f b r}(\Gamma \mid\right.$ $\Gamma)$ ) By applying Theorem 6.3 to $\Gamma$, we conclude that $z \in Z\left(S^{e f r}(\Gamma \mid \Gamma)\right)$.

Proof of Theorem 8.2. Suppose that the subgame $\Gamma$ starts at period $L$. The result follows from the fact that the backwards rationalizability procedure applied to $\Gamma$ coincides with the backwards rationalizability procedure applied to $\hat{\Gamma}$ for periods $m \geq L$, when restricted to information sets within $\Gamma$.

Proof of Corollary 8.2. Proof is given in the text above the statement of this corollary.
Proof of Corollary 8.3. Follows immediately from Corollaries 8.1 and 8.2.

[^1]:    ${ }^{1}$ It is often claimed that backward induction first appeared in Zermelo (1913) in the proof of his famous theorem on chess. However, Zermelo did not assume a stopping rule for chess, and hence the game he considered did not have a finite horizon. Therefore, he could not use backward induction.

[^2]:    ${ }^{2}$ This would be a special instance of an extensive-form game with unawareness. See, for example, Heifetz, Meier and Schipper (2013).

[^3]:    ${ }^{3}$ What we call a "strategy" is sometimes called a "plan of action" in the literature (Rubinstein (1991)), and what we call a "complete strategy" is often called a "strategy". The advantage of the notion of "strategy" we use here, is that it reduces the description of strategies and strategy sets when carrying out any of the rationalizability procedures.

[^4]:    ${ }^{4}$ By abuse of notation, we write $b_{i}(h)\left(s_{-i}\right)$ instead of $b_{i}(h)\left(\left\{s_{-i}\right\}\right)$.

[^5]:    ${ }^{5}$ If $m>L$ then $\tau<m$, since $h$ is always reachable by a strategy in $S_{i}^{m-1.0}=S_{i}^{m \cdot K_{m}}$.

[^6]:    ${ }^{6}$ In the literature, such type spaces are sometimes called terminal.

[^7]:    ${ }^{7}$ Note that if $h \notin H_{i}\left(s_{i}\right) \cap H^{\tau}$ for all $\tau \geq m$, then $s_{i}$ is (vacuously) optimal for every type of player $i$ from period $m$ onwards.

[^8]:    ${ }^{8}$ Instead of starting with extensive-form rationalizability one could also start with some other concept, and then impose exogenous restrictions on the beliefs. Catonini (2019) uses extensive-form rationalizability as the focal concept here, but his analysis allows it to be replaced by any other rationalizability concept for dynamic games as well.

[^9]:    ${ }^{9}$ See, for instance, the classical Battle-of-the-Sexes game with an outside option, which is the game that starts at $h_{2}$ in Figure 2. In that game, extensive-form rationalizability uniquely yields the forward induction outcome $(c,(f, h))$, whereas backwards rationalizability also allows for the outcomes $(c,(e, h))$ and $d$.

[^10]:    ${ }^{10}$ We thank Pierpaolo Battigalli and Emiliano Catonini for pointing this out to us.

[^11]:    ${ }^{11}$ Though extensive-form rationalizability applied to the smaller game might also allow for more outcomes of the smaller game.
